Research Study Title: 1989 Roadway Congestion Estimates and Trends

16. Abstract
This research report is the fifth year continuation of a six year research effort focused on quantifying urban mobility. This study contain the facility information for 50 urban areas throughout the country. The database used for this research contains vehicle-miles of travel, urban area information, and facility mileage data from 1982 to 1990. Various federal, state, and local agencies provided the information used to update and verify the primary database. The primary database and source of information is the Federal Highway Administration's Highway Performance Monitoring System (HPMS).

Vehicle-miles of travel and lane-mile data were combined to develop Roadway Congestion Index (RCI) values for 50 urban areas including the seven largest in Texas. These RCI values provide an indicator of the relative mobility level within an urban area.

An analysis of the impacts and cost of congestion were also performed using travel delay, increased fuel consumption, and additional facility lane-miles as measures of urban mobility. Congestion costs were estimated on an areawide, per registered vehicle, and per capita basis.

ABSTRACT

This research report is the fifth year of a six year research effort focused on quantifying urban mobility. This study contains the facility information for 50 urban areas throughout the country. The database used for this research contains vehicle-miles of travel, urban area information, and facility mileage data from 1982 to 1990. Various federal, state, and local agencies provided the information used to update and verify the primary database. The primary database and source of information is the Federal Highway Administration's Highway Performance Monitoring System (HPMS).

Vehicle-miles of travel and lane-mile data were combined to develop Roadway Congestion Index (RCI) values for 50 urban areas including the seven largest in Texas. These RCI values provide an indicator of the relative mobility level within an urban area.

An analysis of the impacts and cost of congestion was also performed using travel delay, increased fuel consumption, and additional facility lane-miles as measures of urban mobility. Congestion costs were estimated on an areawide, per registered vehicle, and per capita basis.

Key Words: Mobility, Congestion, Economic Analysis, Transportation Planning, Travel Delay.

IMPLEMENTATION STATEMENT

To determine future highway needs and assist the Texas Department of Transportation in planning, it is desirable to measure and monitor the severity of congestion in the large Texas metropolitan areas. This report provides a quantification of those congestion levels and the economic impact of congestion on urban motorists. The report also presents data on other large metropolitan areas throughout the country to assist in determining nationwide mobility trends. Information in this report should be of value in identifying transportation trends and prioritizing needs for the future.

DISCLAIMER

SUMMARY

This report represents the fifth year of a planned six-year study to measure and monitor urban mobility in 50 urbanized areas throughout the United States. This research study estimates the level of congestion in the seven largest Texas urban areas and 43 other areas representing a cross-section of urban areas throughout the country. Quantitative estimates of mobility levels allow comparisons of transportation systems in the various urbanized areas and assist the transportation community in analyzing urban mobility.

The level of congestion in an urban area was estimated using procedures developed in previous research (1,2,3,4,5,6). The Roadway Congestion Index (RCI) combines the daily vehicle-miles of travel per lane-mile (DVMT) for freeways and principal arterial street systems in a ratio comparing the existing DVMT to calculated DVMT values identified with congested conditions. Equation S-1 illustrates how the areawide and congested level DVMTs are combined into the RCI values for each urban area.

$$\text{Roadway Congestion Index} = \frac{\left[\text{Freeway VMT/Ln.-Mi.} \times \text{Freeway VMT} + \text{Prin Art Str VMT/Ln.-Mi.} \times \text{Prin Art Str VMT}\right]}{\left[13{,}000 \times \text{Freeway VMT} + 5{,}000 \times \text{Prin Art Str VMT}\right]} \qquad \text{Eq. S-1}$$

An RCI value of 1.0 or greater indicates that congested conditions exist areawide. It should be noted that urban areas with areawide values less than 1.0 may have sections of roadway that experience periods of heavy congestion, but the average mobility level within the urban area could be defined as uncongested. The RCI analyses presented in this report are intended to evaluate entire urban areas and not specific locations. The nature of the RCI equation (Eq. S-1) is to underestimate point or specific facility congestion if the overall system has "good" operational characteristics.

Areawide Mobility

Table S-1 combines the freeway and principal arterial street system DVMT and DVMT per lane-mile into the 1990 estimated roadway congestion index (RCI). The eleven most congested urban areas in the study are displayed. The RCI values range from 1.55 (Los Angeles) to 1.12 (Houston and New Orleans). All of these urban areas have surpassed the point (1.0) at which undesirable levels of congestion occur.

Table S-1. 1990 Roadway Congestion Levels

Urban Area	Freeway / Expressway		Principal Arterial Street		Roadway[3] Congestion Index	Rank
	DVMT[1] (1000)	DVMT/[2] Ln-Mile	DVMT[1] (1000)	DVMT/[2] Ln-Mile		
Los Angeles CA	110,350	21,100	80,370	6,480	1.55	1
Washington DC	25,340	16,610	19,560	8,500	1.37	2
San Fran-Oak CA	42,590	17,820	14,000	6,110	1.35	3
Miami FL	8,570	14,170	15,810	7,620	1.26	4
Chicago IL	38,030	15,680	29,050	6,980	1.25	5
San Diego CA	27,690	16,050	9,340	5,460	1.22	6
Seattle-Everett WA	18,920	15,640	9,130	5,800	1.20	7
San Bernardino-Riv CA	14,580	16,290	10,150	4,740	1.19	8
New York NY	82,920	14,050	52,060	6,890	1.14	9
Houston TX	28,230	14,700	10,830	5,080	1.12	10
New Orleans LA	4,970	13,810	4,100	6,560	1.12	10

The ten urban areas which have experienced the greatest growth in congestion between 1982 and 1990 are displayed in Table S-2. The RCI values reflect the level of congestion occurring in the urban areas. San Diego experienced a 56 percent increase in congestion during the nine year period. The congestion increase rate in all cities in the top ten exceeded two percent per year.

Table S-2. Fastest Congestion Growth Areas

Urban Area	Year									Percent Change 1982 to 1990
	1982	1983	1984	1985	1986	1987	1988	1989	1990

The twelve urban areas with the smallest growth in congestion between 1982 and 1990 are shown in Table S-3. Phoenix, Houston, and Detroit all experienced decreases in congestion with Phoenix showing the greatest decrease (10 percent). Congestion increases in these areas were less than one percent per year.

Table S-3. Slowest Congestion Growth Areas

Urban Area	Year									Percent Change 1982 to 1990
	1982	1983	1984	1985	1986	1987	1988	1989	1990

Source: TTI Analysis

Table S-4 combines existing lane-miles on both freeway and principal arterial streets with recent annual growth rates (1987 to 1990) of the daily vehicle-miles travelled (DVMT) on these facilities to produce the number of additional lane-miles which would be necessary to avoid increases in areawide congestion. This value illustrates the amount of roadway that would have to be added *every year* to maintain a constant congestion level. Los Angeles would require 665 lane-miles (197 freeway, 468 principal arterial street) to maintain current levels of mobility.

The urban area with the smallest additional lane-miles in this summary group, San Francisco-Oakland, would require 126 lane-miles (64 freeway, 62 principal arterial street). Roadway mileage has not been constructed at these rates in most cities in the recent past, indicating a need to pursue other methods to improve mobility.

Table S-4. Roadway Necessary to Maintain Constant Congestion Levels

Urban Area	Existing (1990) Lane-miles		Average Annual VMT Growth (%)[1]	Annual Additional Lane-Miles Needed		Rank[2]
	Freeway	Prin. Arter.		Freeway	Prin. Arter.	
Los Angeles CA	5,230	12,405	3.8	197	468	1
New York NY	5,900	7,560	3.4	201	257	2
Chicago IL	2,425	4,160	6.3	152	261	3

[1]Average Annual Growth rate of Freeway and Principal Arterial Streets DVMT between 1987-1990
[2]Ranked by total of freeway and principal arterial street lane-miles.

See Table 8 for complete listing of urban areas.
Source: TTI Analysis

The urban areas with the highest congestion costs are shown in Table S-5. The total congestion costs are comprised of delay and fuel costs. The delay and fuel costs have components related to the type of delay (recurring or incident) that occurs in the urban area. Los Angeles and New York had the highest total congestion costs with values of $7.67 billion and $6.56 billion, respectively. The tenth urban area in the table, Seattle-Everett, had a total congestion cost of $1.14 billion.

Table S-5. Component and Total Congestion Costs By Urban Area for 1990

Urban Area	Annual Cost Due to Congestion ($Millions)					Rank
	Recurring Delay	Incident Delay	Recurring Fuel	Incident Fuel	Delay&Fuel Cost	
Los Angeles CA	3,000	3,530	530	620	7,680	1
New York NY	1,950	3,630	350	640	6,570	2
San Fran-Oak CA	1,050	1,330	190	240	2,810	3
Washington DC	760	1,260	130	220	2,370	4
Chicago IL	900	1,040	160	190	2,290	5
Houston TX	600	810	100	140	1,650	6
Detroit MI	510	800	80	130	1,520	7
Boston MA	330	910	60	160	1,460	8
Philadelphia PA	430	570	70	90	1,160	9
Seattle-Everett WA	420	550	70	100	1,140	10

See Table 16 for complete listing of urban areas.
Source: TTI Analysis and Local Transportation Agency Reference

Congestion costs can be used in relation to registered vehicles to show the economic impact on each automobile in the urban area. Table S-6 lists the top ten congestion costs per registered vehicle for 1990. Washington D.C. ranks first with a cost of $1,420 per vehicle. Dallas and Houston each have costs of $750 per vehicle, or approximately $3 per workday.

Table S-6. 1990 Congestion Cost per Registered Vehicle

Urban Area	Congestion Cost Per Registered Vehicle	Rank
Washington DC	$1,420	1
San Bernardino-Riv. CA	$1,320	2
New York NY	$1,090	3
Los Angeles CA	$ 980	4
San Jose CA	$ 960	5
San Fran-Oak CA	$ 930	6
Boston MA	$ 880	7
Seattle-Everett WA	$ 880	8
Dallas TX	$ 750	9
Houston TX	$ 750	10

See Table 17 for complete listing of urban areas

Source: TTI Analysis

Expressing congestion costs on a per capita basis illustrates the congestion "tax" paid by residents (Table S-7). The highest 1990 cost per capita occurred in San Bernardino-Riverside with a cost per capita of $880. Miami had the smallest cost per capita of the top ten urban areas with a cost of approximately $2 per capita for each workday.

Table S-7. 1990 Congestion Cost per Capita

Urban Area	Congestion Cost Per Capita	Rank
San Bernardino-Riv CA	$ 880	1
Washington DC	$ 770	2
San Fran-Oak CA	$ 760	3
San Jose CA	$ 690	4
Los Angeles CA	$ 670	5
Seattle-Everett WA	$ 660	6
Dallas TX	$ 570	7
Houston TX	$ 570	8
Atlanta GA	$ 530	9
Miami FL	$ 520	10

See Table 17 for complete listing of urban areas
Source: TTI Analysis

By arranging the urban areas into groups based on characteristics such as population size, it is possible to view the effects of congestion on the different groups of areas in the study. Table S-8 shows the vehicle hours of delay present in the study areas. The largest group (Chicago, Los Angeles, New York) has vehicle delay of at least 110 hours per person annually. The smallest group, comprised of areas with populations of 800,000 or less, has vehicle delay of 50 hours per person. This seems to indicate that the average congestion impact is twice as large on the average resident of a city with a population greater than 7 million than in the group of the smallest cities in our study.

Table S-8. 1990 Vehicle Delay for Population Groups

Population Group	Average Delay (Vehicle-hours)	Total Delay per 1000 Persons (Veh-Hours)
Fifth Group	1,272,570	110
Fourth Group	302,520	100
Third Group	141,830	90
Second Group	65,050	60
First Group	31,510	50

INTRODUCTION

Congestion within the inner city has long been recognized as a severe problem. Congested streets and freeways have forced residents and businesses to relocate in the surrounding suburbs. Relocating to the suburbs, however, proved to be only a temporary solution to metropolitan area congestion problems. Congestion has expanded into the suburbs, with street systems designed for service to residential areas overburdened with traffic headed to large shopping malls and business parks. Urban transportation systems have been required to serve more travel needs between suburbs and fewer trips to or from downtown business districts.

The decline in urban mobility resulting from congestion has become a major concern not only to the transportation community, but also to the motoring public and business community. Measuring congestion provides an understanding of the phenomenon which assists transportation professionals, policy makers, and the general public in effectively communicating problems and developing necessary transportation system improvements.

Purpose of Congestion Research

Why should we research and investigate effects of urban congestion? Quite simply, old solutions are not working any more. In the past, the mobility situation in most metropolitan areas has had the limited choices of controlling area growth, large expenditures for general use and transit facility improvements, or accepting decline in the quality of transportation in the cities and suburbs. Transportation professionals, policy makers, the media, and the general public generally view these options as undesirable. In more recent years, cities have encouraged the use of various aspects of travel demand management (TDM). Some of these techniques reduce vehicle-miles of travel, thus reducing congestion, while others only modify demand by shifting the time of travel.

Whether cities use more traditional techniques of congestion management or the more recent techniques such as TDM, measuring congestion is still a vital step in understanding the problems of congestion and aiding in the development of effective solutions to the urban mobility problem.

Previous research efforts of this series developed a quantitative procedure to compare traffic volumes and roadway mileage. The procedure estimates the mobility levels within an urban area and permits the comparison of transportation systems from year to year and area to area.

Congestion Research Background

This research study uses existing data from federal, state, and local agencies to develop planning estimates of the level of mobility within an urban area. The analyses presented in this report are the result of previous research (1-6) conducted at the Texas Transportation Institute. The methodology developed by the previous research provides a procedure which yields a quantitative estimate of urbanized area mobility levels, utilizing generally available data, while minimizing the need for extensive data collection.

The methodology primarily uses the Federal Highway Administration's Highway Performance Monitoring System (HPMS) database with supporting information from various state and local agencies. Currently, the database developed for this research contains vehicle travel, population, urban area size, and facility mileage from 1982 to 1990. Primarily, vehicle travel and vehicle travel per lane-mile are used as the basis of measuring urban mobility and comparing areawide roadway systems.

Report Organization/Content

There have been some changes incorporated in this report that differentiate it from others in this series (3,4,5,6). Recent congestion reports (3,4,5) contained detailed discussions of development for both the roadway congestion index (RCI) and cost methodology, including extensive appendices containing data compiled during the study. This research report will focus on the results of analyses estimating 1990 congestion levels and trends displayed by the data from 1982 to 1990. In addition, the metropolitan areas in the study have been grouped by such factors as population, land area, and population density to display trends that exist between these various groups. Information on the methodology is available in the previous reports.

This report summarizes and discusses urban mobility levels in 50 metropolitan areas throughout the United States. Seven of the areas studied represent the largest metropolitan areas in Texas; the remaining 43 areas are located in 27 states (Figure 1). These 50 areas include nearly all of the urban areas in the United States with populations of 800,000 or more that have a significant amount of congestion. Figure 1 illustrates the geographic regions used in the analyses to combine urban areas studied. There are three major topics addressed in this report: areawide mobility, the impacts of congestion, and the cost of congestion. The following are brief descriptions of the information included within each of these topics.

Areawide Mobility

Understanding the reasons for the type and scope of urban congestion problem has become important to transportation planners and policy makers. Obtaining quantitative estimates of mobility levels that allow the comparisons of transportation systems provides a tool to analyze the differences between different transportation systems and urban areas. This section discusses the trends in urban development, travel and mileage statistics, and the 1990 Roadway Congestion Index (RCI) values for 50 urban areas included within the study.

Impacts of Congestion

The most quantifiable impacts of congestion are additional capacity required to eliminate congested conditions and the amount of time spent by motorists in congestion. This section discusses the relationship between the freeway and principal arterial street systems and annual traffic growth. Travel delays are also addressed in this section. Delay, the most apparent impact of congestion to the motoring public, may be categorized into two general areas -- recurring and incident. The impacts of travel delay and the relationship with an urban area's RCI are analyzed.

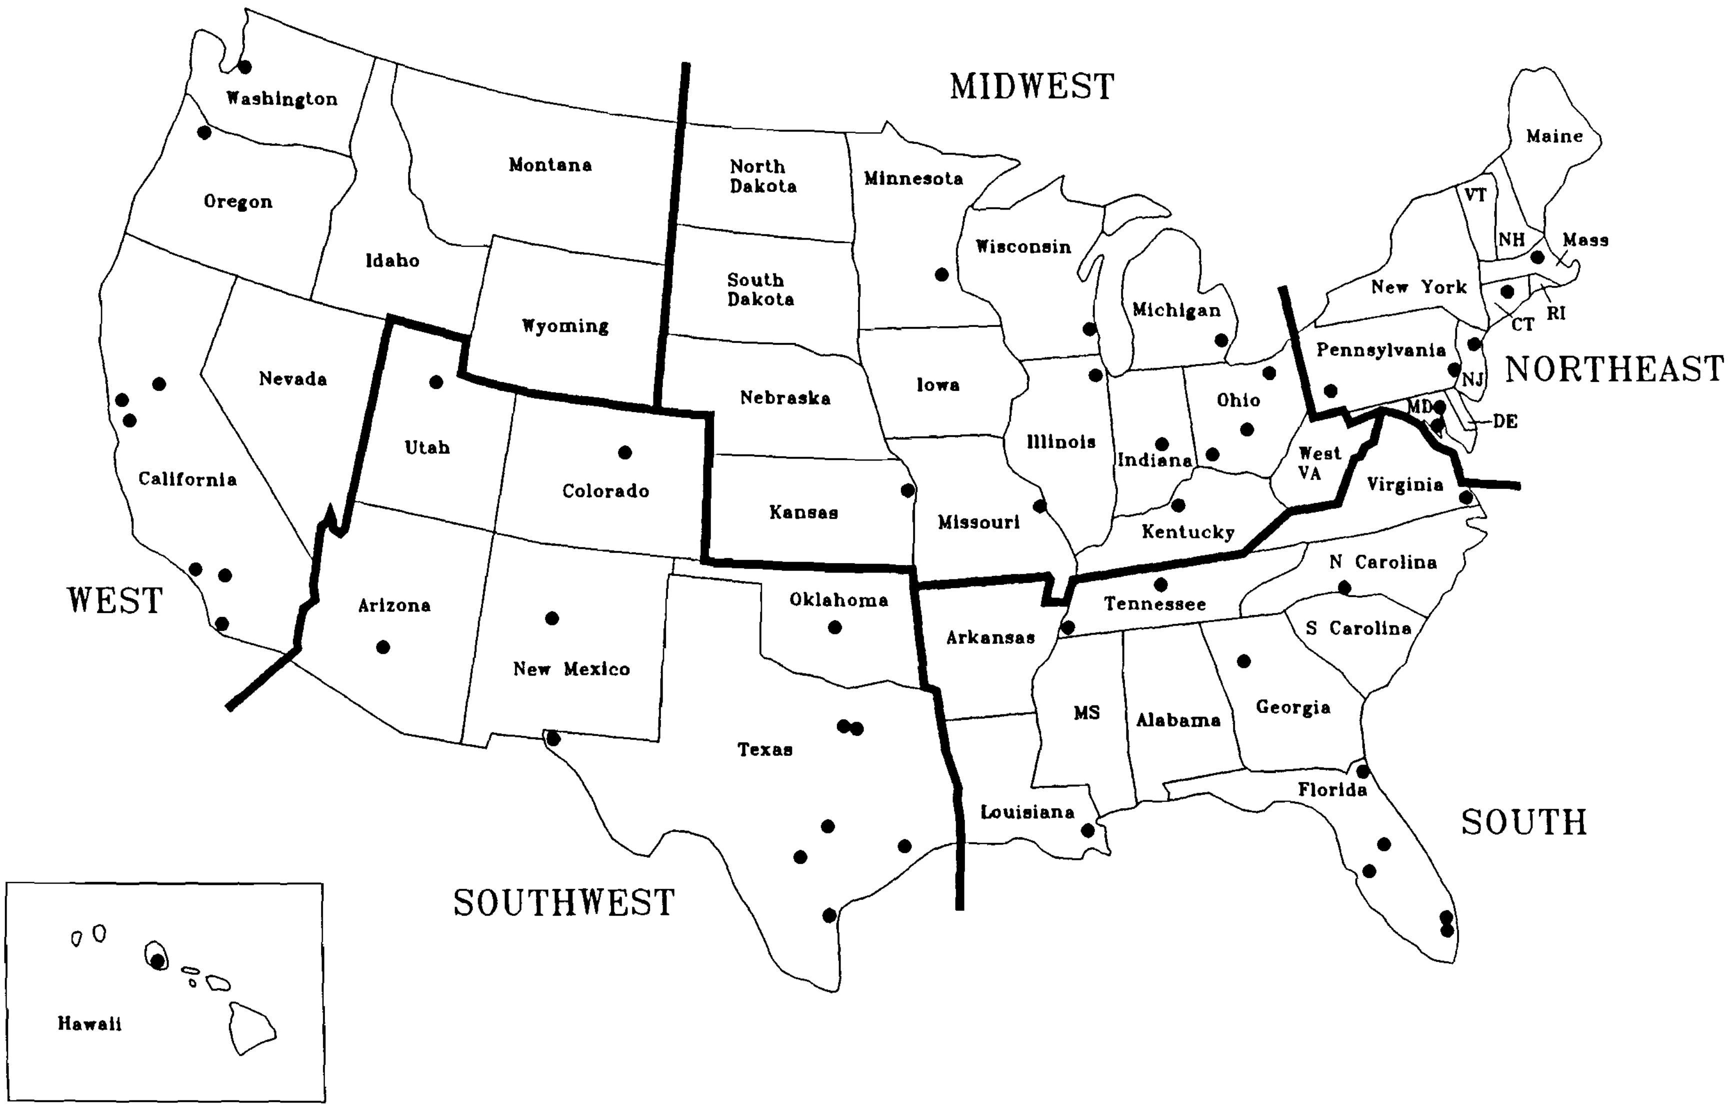

Figure 1. Regional Area Map

Cost of Congestion

Within this section the economic impact of congestion was estimated for the 50 urban areas studied. Congestion costs have two components -- delay and wasted fuel. Estimating the costs associated with congestion provides another tool for comparing urban mobility from one area to another. More importantly estimating congestion costs allows a method of tracking changes in congestion levels and their impact on an urbanized area over an extended period of time.

AREAWIDE MOBILITY

A 1989 report (7) identified several trends shaping traffic congestion. The interrelated forces impacting the nature and severity of congestion identified in that report include: (1) suburban development, (2) the economy, (3) the labor force, (4) automobile usage, (5) percent of truck traffic, and (6) the highway infrastructure. The following is an example of how these forces interact:

> "Trends in suburban and economic development have supported and generated increased automobile usage and truck traffic. This has resulted in increasing traffic congestion in many metropolitan areas throughout the country" (7).

Trends in Urban Development

Most metropolitan areas have experienced dynamic suburban growth since the 1960s. Suburban development was encouraged by the prevailing desire to live away from the inner city and yet be in close enough proximity to enjoy urban amenities. This evolutionary process begins with families and then expands to commercial services and jobs. The process shapes traffic congestion in most large and small metropolitan areas by altering the commuting patterns.

The demands placed on the existing highway infrastructure in general and by the migration of the population and employment opportunities have not been met by new facility construction. Demands for suburban traffic movement, increasing vehicle-miles of travel, and more freeway access points have greatly altered the function of the freeway/expressway system in most metropolitan areas. Increases in delay are the result of the roadway system capacity not increasing to meet new demands.

The decline in new facility construction during the past 20 years may be attributed to reduced funding, increased construction costs, and public resistance to building and widening transportation facilities. These factors have promoted lower levels of mobility and greater dispersion of the metropolitan area's population. In recent years, an increasingly negative perception of the mobility level has renewed interest in the transportation infrastructure. This same perception of the transportation infrastructure has also increased the desire of the transportation community, general public, policy makers, and numerous others to understand the causes, effects, and solutions to urban congestion.

Travel and Mileage Statistics

Previous TTI research (3,4,5,6) used daily vehicle-miles of travel (DVMT) per lane-mile of freeway and principal arterial street as indicators of urban congestion levels. The previous studies established the values of 13,000 DVMT per freeway lane-mile and 5,000 DVMT per (principal arterial street) lane-mile as the thresholds for undesirable congestion levels. Briefly, when areawide freeway travel volumes exceed an average of 13,000 DVMT per lane-mile, undesirable levels of congestion occur. The corresponding level of service is reached on principal arterial streets when travel volumes average 5,000 DVMT per lane-mile.

This section presents comparisons of mobility within geographic regions and between individual urban areas using DVMT per lane-mile statistics.

Freeway Travel and Mileage Statistics

Areawide freeway operating statistics are summarized in Table 1. The urban areas are ranked according to the primary congestion indicator, DVMT per lane-mile. Summary statistics for each geographical region are located at the bottom of Table 1.

Eighteen urbanized areas exceeded the 13,000 DVMT per lane-mile level indicating areawide congested conditions on the freeway systems. Of the ten urban areas with the highest DVMT per lane-mile values, five have experienced congested freeway systems since 1982. An additional eleven urban areas studied have DVMT per lane-mile values within ten percent of the 13,000 level. Urban areas with travel demands in this range would only have to experience moderate to slight increases in travel demands to cause their freeway systems to operate under congested conditions.

Table 1. 1990 Freeway Mileage and Travel Volume

Urban Area	DVMT[1] (1000)	Lane-Miles	Avg. No. Lanes	DVMT/[2] Ln-Mile	Rank[3]
Los Angeles CA	110,350	5,230	8.2	21,100	1
San Fran-Oak CA	42,590	2,390	6.8	17,820	2

Note: [1] Daily vehicle-miles of travel
[2] Daily vehicle-miles of travel per lane-mile of freeway
[3] Rank value of 1 associated with most congested condition
Ranked by DVMT/Lane-mile

Source: TTI Analysis and Local Transportation Agency References

The summary statistics at the bottom of Table 1 show average DVMT per lane-mile values by geographic region. Every region (except the Western region) has DVMT per lane-mile values below the 13,000 level. Comparing these statistics with the similar 1989 analysis (6) shows that the average DVMT per lane-mile value for every geographic region (except Southern) has increased from one to two percent. Over the same period the Southern DVMT per lane-mile average has decreased slightly (less than one percent).

Principal Arterial Street Travel and Mileage Statistics

Table 2 shows the operating characteristics of the principal arterial street system for each urban area included in this study. As in Table 1, Table 2 ranks urban areas by travel demand per lane-mile and contains regional summary statistics. In 1990, 34 of the urban areas studied experienced DVMT per lane-mile levels exceeding 5,000. Of these 34 urban areas, 27 have had travel demands exceeding 5,000 DVMT per lane-mile since 1982.

The summary statistics show that all the regional averages except the Texas average exceed the 5,000 DVMT per lane-mile level. In contrast to the freeway values, the arterial street statistics indicate more congested operation on the arterial street systems in this study. The regional average travel demand on principal arterial street systems increased between one and three percent from 1989 levels in all of the geographic regions studied, except Texas. Urban areas in Texas showed no change in travel demand from 1989.

Relationship Between Travel Demand and Urban Area Population/Size

In previous reports (4,5,6), reference was made to relationships of DVMT and facility lane-miles to urban area population and size. The relationship between travel demand, lane-miles, and population indicates on what facilities motorists place the highest demand, while the relationship between DVMT, facility lane-miles, and area size indicates the density of both the freeway and principal arterial street systems.

Tables 3 and 4 show the relationship between DVMT and urban area population. In both tables, the urban areas are ranked by DVMT and facility lane-miles per person. Comparison of the summary statistics of these tables indicates:

- The DVMT per person value shows each geographic region studied depends on the freeway system for service of the majority of travel demand.
- The freeway systems in the Texas region and the principal arterial street systems in the Southern region are the most dense across the regions.
- The greatest travel per capita occurs on the freeways in the Western region and on the principal arterial street system in the Southern region.

Roadway Congestion Index Values, 1990

Table 5 combines the freeway and principal arterial street system DVMT and DVMT per lane-mile values into the estimated 1990 Roadway Congestion Index (RCI). Equation 1 illustrates how those values are used to calculate the RCI value for individual urban areas. The RCI value is a relative measure of the level of congestion for a given urban area. An RCI value of 1.0 or greater indicates an undesirable areawide congestion level.

$$\text{Roadway Congestion Index} = \frac{\left[\text{Freeway VMT/Ln.-Mi.} \times \text{Freeway VMT} + \text{Prin Art Str VMT/Ln.-Mi.} \times \text{Prin Art Str VMT}\right]}{\left[13{,}000 \times \text{Freeway VMT} + 5{,}000 \times \text{Prin Art Str VMT}\right]} \qquad \text{Eq. 1}$$

1990 Roadway Congestion Index Estimates

Of the 50 urban areas studied, 24 have RCI values exceeding 1.0. RCI values for the ten most congested urban areas range from 1.55 (Los Angeles) to 1.12 (Houston and New Orleans). Twelve urban areas have estimated RCI values ranging between 0.99 and 0.90 indicating the potential approach of undesirable congestion levels. These areas may not currently experience undesirable levels of congestion, however, traffic growth rates indicate congestion levels could become undesirable within the next few years in many of these cities.

The Western region has the highest average RCI value of 1.19. The only other regional average exceeding 1.0 was the Northeastern (1.05). The Southwestern, Southern, and Midwestern regions have average RCI values below 1.0.

Houston (tied at 10th) was the only urban area studied in Texas which was included in the ten most congested urban areas. Dallas (tied at 17th) was the second highest ranked area within the state. Austin was ranked (tied at 30th) as the only other urbanized area in the state in the top 30.

Roadway Congestion Index Growth, 1982 to 1990

Roadway congestion index values for all 50 urban areas from 1982 to 1990 are summarized in Table 6. During the study period, San Diego, San Francisco, and Salt Lake City were estimated to have experienced the fastest increase in congestion, while Phoenix, Detroit, and Houston have experienced the smallest. Of the urban areas in Texas, Dallas has the largest increase in RCI from 1982 levels (25 percent). Approximately 40 percent of the urban areas have experienced between 17 and 23 percent growth between 1982 and 1990. The summary statistics show that no geographic region experienced a decrease in average 1990 RCI values from 1989 levels.

Figure 2 illustrates trend data for the Texas urban areas studied. This figure graphically shows the improving trend of congestion in Houston which is currently below 1982 levels. Dallas, Fort Worth, and Austin experienced increasing congestion levels until 1986. Since that time, congestion levels have been relatively constant. San Antonio, El Paso, and Corpus Christi exhibited a slightly increasing trend in their RCI values between 1987 and 1990.

Table 6. Roadway Congestion Index Values, 1982 to 1990

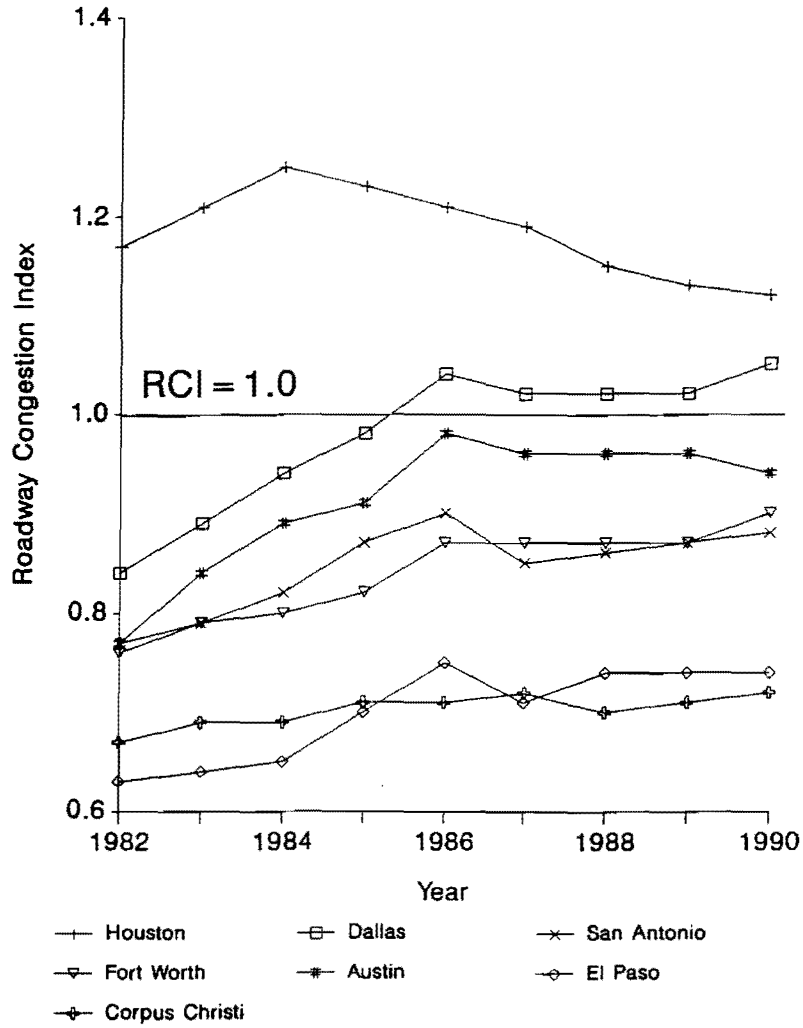

Figure 2. Texas Urban Area RCIs 1982 - 1990

IMPACTS OF CONGESTION

The most quantifiable impacts of congestion are additional capacity required to eliminate the congested conditions and the time spent in congested traffic conditions. Additional capacity required annually to maintain existing traffic density levels indicates the burden of congestion on the transportation infrastructure and available roadway funds. Travel delay is the measure of inconvenience congestion imposes on the motoring public.

Travel Volumes

Freeway and principal arterial street systems are the primary facilities selected for expansion because the majority (60 to 70 percent) of an urban area's DVMT is served by these facilities. Table 7 illustrates the percentage of daily VMT served by the freeway and principal arterial street systems. While the average amount of daily VMT served by these facilities is significant in all areas, comparing the percentage for each urban and geographic area (Table 7) does give some indication of the facility carrying the majority of the demand.

Figure 3 illustrates the regional daily VMT served by the freeway system for each geographical region studied. During the study period, the percentages have remained relatively constant for each region. Motorists in the Western region place the highest demand on the freeway system, while the Southern region places the lowest. Motorists in the Texas and Midwestern regions place the second highest average demand on the freeway system of all geographic regions.

Figure 4 shows the corresponding demands placed on the principal arterial street systems. This figure shows that the highest demand on the principal arterial street system is placed by the Northeastern and Southern regions. The Texas and Midwestern regions depend the least on this system for urban travel. Each of the regions have shown a decrease in the percentage of DVMT serviced by principal arterial streets from 1982 to 1990.

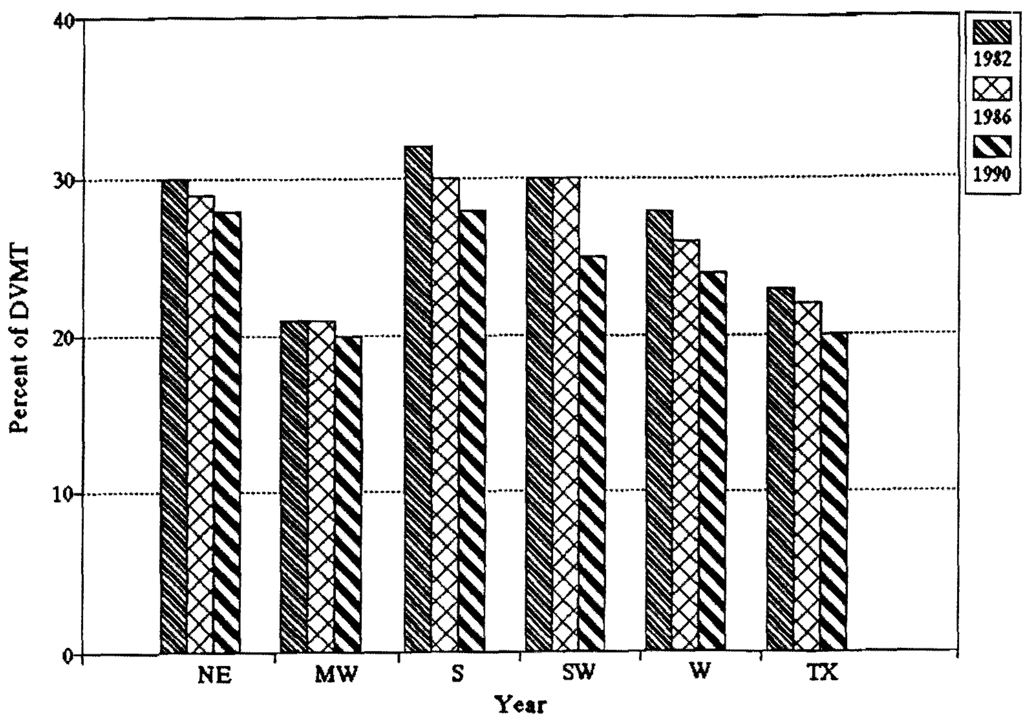

Figure 4. Principal Arterial Street Percentage of DVMT

Additional Capacity

The addition of capacity to alleviate congestion is becoming more difficult in many urban areas, but it can be an effective tool in addressing congestion problems. As Table 8 illustrates, this practice is difficult to maintain over many years. The annual DVMT growth rate is applied to the existing system length to show the amount of additional lane-mileage that is required to prevent congestion levels from increasing. The system capacity has to increase by the same percentage as traffic volume for congestion levels to be maintained.

For example, New York would require 201 additional lane-miles of freeway and 257 lane-miles of principal arterial streets per year to maintain the 1990 congestion level with the 3.4 percent growth in DVMT it experienced between 1987 and 1990.

The amount of additional capacity required for freeway and principal arterial street systems make it apparent that the construction of additional lane-miles as the sole alternative to alleviate congestion is not feasible for many urban areas. Regardless of whether the majority of an area's travel is served by the freeway or principal arterial street system, roadway construction must be combined with a range of other improvements and programs to address the needs of severely congested corridors.

Travel Delays

Travel delay is the most apparent impact of congestion to the motoring public. Analyses of delay have generally been divided into two estimates -- recurring and incident. Recurring delay occurs due to normal daily operations. The most common example of recurring delay is the increased travel time during peak periods of operation.

The other type of delay related to congestion is incident delay. Incident delay is caused by accidents, breakdowns, or other occurrences which decrease roadway capacity. When congestion levels increase (creating higher RCI values), it is the recurring delay that is directly affected. While incident delay is not directly related to or caused by congestion, the delay resulting from incidents significantly increases under congested conditions.

Table 8. Illustration of Annual Capacity Increase Required to Prevent Congestion Growth

[1] Average Annual Growth Rate of Freeway and Principal Arterial Streets traffic volume between 1987 and 1990.

Source: TTI Analysis

Tables 9 and 10 categorize delay by the severity level (moderate, heavy, and severe) for freeways and principal arterial street systems. The congestion categories are based on average daily traffic volumes per lane (9). Table 11 summarizes the vehicle-hours of delay by type and urban area. These values were also used to estimate the economic impacts of congestion.

The rankings in Table 11 are similar to the rankings by RCI (Table 5). Vehicle-hours of delay are also ranked after being normalized by population. The total delay per 1000 persons quantifies the congestion levels independent of urban area size and population. Ranking delay in this manner allows an evaluation similar to the RCI in that it analyzes the effects on individual motorists. Summary statistics show that the Western and Northeastern regions have the largest average per capita delay, while the midwestern region has the least.

COST OF CONGESTION

Another method of assessing impact is to look at economic factors. Two quantities closely related to congestion are delay and wasted fuel. This chapter presents estimates of the value of traffic delay and fuel wasted due to congested traffic for the 50 study areas.

Economic Impact Estimates

Estimates of congestion costs were based on the congested peak-period VMT on freeways and principal arterial street systems. Table 12 lists the freeway and principal arterial street DVMT and populations utilized in the congestion cost estimates. The data shown in this table were obtained through the HPMS database and various state and local agencies.

The two primary components of the congestion cost estimates were traffic delay and excess fuel consumption. Congestion severity affects both the travel time and fuel consumption by decreasing the speed and vehicle fuel efficiency as congestion becomes worse. The congestion categories used to estimate vehicle-hours of delay (Table 11) were also used to estimate fuel consumption. The vehicular speeds used in the congestion cost estimates are shown in Table 13.

Congestion cost estimates also used several study constants and urban area variables in the calculations. The five values held constant for all urban areas in the congestion cost analyses and calculations included:

1. Average vehicle occupancy -- 1.25 persons per vehicle
2. Working days per year -- 250 days
3. Average cost of time (9) -- $10.00 per person-hour (1990 value)
4. Commercial vehicle operating cost (10) -- $1.95 per mile (1990 value)
5. Vehicle mix -- 95 percent passenger and 5 percent commercial

Table 12. Summary of 1990 DVMT Values and Population for Congestion Cost Estimates

Table 13. Speed Relationships with Average Daily Traffic per Lane Volumes

Functional Class	Parameters	Severity of Congestion[1,2]		
		Moderate	Heavy	Severe
Freeway/Expressway	ADT/Lane	15,000 - 17,500	17,501 - 20,000	Over 20,000
	Speed (mph)[3]	38	33	30
Principal Arterial Streets	ADT/Lane	5,750 - 7,000	7,001 - 8,500	Over 8,500
	Speed (mph)[3]	28	25	23

Note: [1]Assumes congested freeway operation when ADT/Lane exceeds 15,000.
[2]Assumes congested principal arterial street operations when ADT/lane exceeds 5,750.
[3]Value represents a weighted average

Source: TTI Analysis and Houston-Galveston Regional Transportation Study

Four area specific variables were also used in the congestion cost estimates. These variables are briefly described below:

1. Daily vehicle-miles of travel (DVMT) -- the average daily traffic (ADT) of a section of roadway multiplied by the length (in miles) of that roadway section.

2. Fuel cost -- the state average fuel cost per gallon for 1990.

3. Registered vehicles -- the number of registered vehicles as reported by local agencies.

4. Population -- estimated using the 1990 Census Bureau estimates and HPMS data.

These variables were used to estimate and analyze the effects of congestion in each urban area. The economic impact of congestion was stated in terms of annual congestion cost, cost per registered vehicle, and cost per capita. Previous reports have included additional insurance costs resulting from operating a vehicle in larger metropolitan areas. Due to the difficulty in obtaining data from the insurance industry, these costs were omitted from this cost analysis.

Economic Analysis

While the above variables are used to analyze congestion cost in this study, it should be recognized that some of these cost variables fluctuate with economic trends. The variables -- fuel cost, commercial vehicle operating cost, and the average cost of time -- are updated annually to reflect the change in these costs. Estimates of vehicle-hours of delay and gallons of wasted fuel should be used to analyze congestion trends.

Table 14 gives the total delay in each urban area from 1986 to 1990. Thirty-four of the 50 urban areas had at least a 15 percent growth in delay over the five-year period. Ten of the areas had at least a 50 percent growth in the same period. Sacramento showed a 100 percent increase in delay during this same time. Only two urban areas (Austin and San Antonio) displayed a decrease in delay over this five-year period.

The summary statistics show that only the Midwestern and Texas regions did not have at least a 15 percent growth in delay from 1986 to 1990. The Texas region had no change in delay over this period. The Northeastern and Southern regions showed the largest percent increase in total delay over the five-year period.

As congestion increases, slower vehicle speeds result in increased fuel consumption. The procedure used to estimate the amount of wasted fuel is tied to the average speed values used to calculate vehicle delay. The change in wasted fuel and vehicle delay are, thus, closely related. While this is not appropriate over all speed ranges, it provides reasonable estimates of areawide fuel consumption. The equation used to estimate fuel consumption has a linear relationship to speed.

The amount of fuel which was wasted due to congestion from 1986 to 1990 is shown in Table 15. The summary statistics show that the Northeastern and Southern regions had the highest average growth over the period. The Southwestern and Texas regions were the only two which did not surpass a 15 percent growth in wasted fuel over the five year period.

The component and total congestion costs for each urban area are shown in Table 16. In 1990, the total cost of congestion for the urban areas studied was approximately $43.2 billion. This represents a 10 percent increase in the economic impact of congestion since 1989 ($39.2 billion). The increase in the value of time rate was 8 percent and fuel costs averaged a 9 percent increase. Studywide averages indicate that recurring and incident delay accounted for

approximately 85 percent of an urban area's congestion cost. The average economic burden placed on urban areas in 1990 due to congestion was $860 million, compared to $780 million in 1989.

Thirteen urban areas had total congestion costs equal to or exceeding $1 billion. Of the seven urban areas studied in Texas only two, Houston -- 6th and Dallas -- 11th, ranked in the top fifteen. Congestion in the Texas urbanized areas resulted in a cost of approximately $3.7 billion, a 12 percent increase from 1989 congestion costs.

Table 17 illustrates the estimated economic impact of congestion per capita and per registered vehicle. Viewing congestion costs in relation to population and vehicles provides an estimate of the effects of congestion on the individual. The urban area with the highest per vehicle cost was Washington, D.C. ($1,420 per registered vehicle), while San Bernardino-Riverside had the highest per capita cost ($880 per person). The relationships of these cost estimates to total congestion cost can be seen in Table 18, which illustrates the rankings of urban areas by the annual, per capita, and per registered vehicle costs. The rankings of the cost estimates are fairly consistent with 15 urban areas occupying the top ten positions in all three categories. The 1989 and 1990 rankings of the RCI values and the congestion costs per capita are displayed in Table 19. The change during the past year can be seen in the costs and RCI rankings.

Tables 20 through 27 present estimates of congestion cost from 1986 to 1989. Previously published estimates presented in this series of reports have been revised for some areas to reflect new information. The data in Tables 20 through 27 are the best current information on the delay, fuel and cost values for the years 1986 through 1989. Some of the data missing in 1986 and 1987 was unobtainable because of the various methods of reporting information in the HPMS database.

CONGESTION TRENDS FOR URBAN AREA GROUPS

Previous sections have presented travel, roadway supply, and congestion statistics for individual urban areas and geographic regions across the United States. Other groupings based on population size and population density were used to further examine the various congestion trends that occur between the urban areas and over the past decade. Grouping areas by population size or population density can reveal how the size of a city, or its development characteristics, are related to congestion. This section presents and examines the various congestion trends for the 50 urban areas grouped by population size and population density.

Population Size

The amount of congestion in an urban area is intuitively related to its population. Larger urban centers tend to be more congested and typically have a range of solutions to address transportation problems, indicating a recognition of the problems of relying on roadway solutions. This section presents an analysis of the relationship between population and congestion level.

For the purposes of this analysis, Chicago, New York, and Los Angeles were separated because of their comparatively large populations, and the remaining areas were divided into four approximately even groups based on the 1990 population estimates (Table 28). Chicago, New York, and Los Angeles have populations much greater than the areas in the adjacent group, and the statistics for these three areas would have distorted the true average statistics for the fourth group. The major Texas urban areas are located in three of the groups: Corpus Christi, Austin, and El Paso are in the first group; San Antonio and Forth Worth are in the third group; and, Dallas and Houston fall into the fourth group. Table 28 also shows the 1990 RCI value and percent change in the RCI from 1982 to 1990 for each urban area in the five groups.

Table 28. Urban Area Grouping by Population Size

Urban Area	Population (1000)	Roadway[1] Congestion Index	Percent Change in Roadway Congestion Index, 1982 to 1990

Mileage and Travel Volume Statistics

The average freeway and principal arterial street mileage and travel volumes (DVMT) for the five population groups are shown in Tables 29 and 30. The general trend is increasing average roadway mileage and travel volumes for an increasing population size. Chicago, New York, and Los Angeles (fifth group) have disproportionately higher travel volumes and roadway mileage than the first four groups. The average DVMT per lane-mile, a measure of the severity of congestion, shows that freeway and principal arterial street congestion is more extensive in the larger population groups.

The magnitude of the freeway DVMT per lane-mile values also indicate that, on the average, urban areas in the fourth and fifth groups experience undesirable areawide levels of congestion on the freeway system. The magnitude of the principal arterial street DVMT per lane-mile values suggest that, on the average, all population groups experience undesirable levels of congestion on principal arterial streets.

Table 29. 1990 Freeway Mileage and Travel Volume Grouped by Population

Population Group	DVMT[1] (1000)	Lane-Miles	Avg. No. Lanes	DVMT/ Ln-Mile[2,3]
Fifth Group	77,100	4,520	6.5	16,950
Fourth Group	23,890	1,680	5.8	14,060
Third Group	12,020	940	5.5	12,570
Second Group	8,210	700	5.5	11,850
First Group	4,350	410	5.1	10,630

1990 Roadway Congestion Index Estimates

The components of the Roadway Congestion Index (RCI) equation and the average 1990 RCI values for the five population groups are shown in Table 31. The average RCI values exhibit the general trend of increasing average levels of congestion for increasing urban area population size. The urban areas with large populations (fourth and fifth group) have undesirable levels of congestion (RCI values of 1.11 and 1.31, respectively), while the average for the medium-size areas (third group) is just beginning to indicate areawide congestion (RCI value of 1.01). Smaller urban areas in the first and second groups have average RCI values of 0.89 and 0.93, below what might be considered areawide congestion.

Table 31. 1990 Roadway Congestion Index Values Grouped by Population

Population Group	Freeway / Expressway		Principal Arterial Street		Roadway[3] Congestion Index
	DVMT[1] (1000)	DVMT/[2] Ln-Mile	DVMT[1] (1000)	DVMT/[2] Ln-Mile	
Fifth Group	77,100	16,950	53,820	6,780	1.31
Fourth Group	23,890	14,060	13,390	5,940	1.11
Third Group	12,020	12,570	8,900	5,570	1.01

Roadway Congestion Trends, 1982 to 1990

The average growth in congestion between 1982 and 1990 for the five population groups ranges between 15 and 21 percent (Table 32, Figure 5). Congestion has increased faster in the larger population groups than in the smaller population groups. Interestingly, the average growth in congestion for the smallest study areas in the first group has slightly outpaced growth in the medium to large study areas in the second and third groups.

Table 32. Roadway Congestion Index Values Grouped by Population, 1982 to 1990

Population Group	Year									Percent Change, 1982 to 1990
	1982	1983	1984	1985	1986	1987	1988	1989	1990	
Fifth Group	1.08	1.10	1.12	1.15	1.21	1.23	1.27	1.29	1.31	21
Fourth Group	0.94	0.97	1.00	1.01	1.06	1.08	1.09	1.10	1.11	19
Third Group	0.88	0.90	0.91	0.94	0.96	0.98	0.98	1.00	1.01	15
Second Group	0.81	0.81	0.82	0.84	0.87	0.90	0.92	0.93	0.93	15

Travel Delays

Table 33 illustrates travel delay information for the five population groups. Inspection of the table reveals that the average total delay for Chicago, New York, and Los Angeles (fifth group) exceeds 1.2 million vehicle-hours of delay. This means the total delay is over four times that of the other large urban areas in the fourth group. The general trend for the other groups is one of higher delay for larger population size. The total delay per 1000 persons for the five population groups ranges from 110 to 50 vehicle-hours, with lower delay values in smaller population areas.

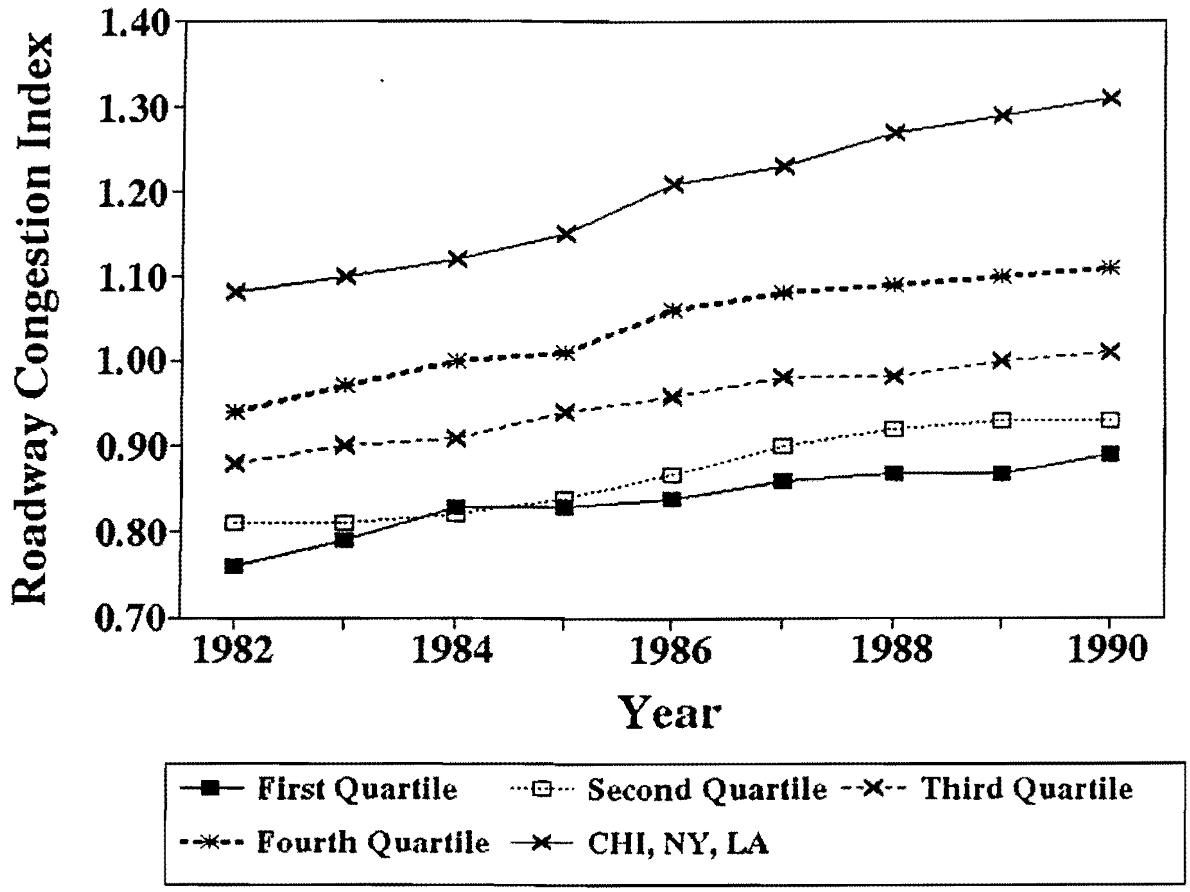

Figure 5. Roadway Congestion Index Values Grouped by Population, 1982 to 1990

Table 33. Total Vehicle Hours of Delay for 1990 Grouped by Population

Population Group	Total Delay (vehicle hours)	Total Delay per 1000 Persons
Fifth Group	1,272,570	110
Fourth Group	302,520	100
Third Group	141,830	90
Second Group	65,050	60
First Group	31,510	50

Costs of Congestion

The congestion cost data presented in Table 16 was summarized to determine the average costs of congestion for the five population groups (Table 34). The larger urban areas in the fourth group had average annual congestion costs exceeding $1.3 billion, while the average congestion cost in the fifth group was more than $5.5 billion. The congestion cost per registered vehicle and per capita are also shown in Table 34. These normalized costs, which could also be called a "congestion tax," are the additional loss of money that congestion imposes upon residents of the urban area. The cost per registered vehicle ranged from $880 to $270 for the five population groups, and the annual cost per capita ranged from $460 to $230 per person. The costs per capita in the fourth and fifth group are much lower than the cost per vehicle, which reflects the lower vehicle ownership rate in urban areas in the Northeast and Midwest that comprise most of the cities in those two groups.

Table 34. 1990 Component and Total Congestion Costs Grouped by Population

Population Group	Annual Cost Due to Congestion ($Millions)			Cost per Registered Vehicle ($)	Cost per Capita ($)
	Delay	Fuel	Total		
Fifth Group	4,680	820	5,510	880	460
Fourth Group	1,110	190	1,300	680	450
Third Group	520	90	610	510	380
Second Group	240	40	280	360	270
First Group	110	20	140	270	230

Population Density

The population density of an urban area provides some indication of the compactness of development. In the United States, a general trend is that older cities in the Northeast and Midwest exhibit more dense development than those cities in the Southern and Southwestern regions. The 50 urban areas in this study were divided into 4 approximately even groups based on the population density (Table 35). Examination of the table reveals that those urban areas with the greatest population density (fourth group) are primarily located in the Northeast or in California. All of the major Texas urban areas are within the first group of population density (1130 to 1755 persons per square mile) with the exception of San Antonio, which falls into the third group. With respect to population density, the urban areas of Chicago, New York, and Los Angeles are comparable to those urban areas in the fourth group and were so included.

Mileage and Travel Volume Statistics

Tables 36 and 37 present the average freeway and principal arterial street mileage and DVMT for the four population density groups. The first three groups have relatively comparable travel and roadway characteristics, while the fourth group has much greater travel volumes and roadway supply for both freeways and principal arterial streets. The average freeway DVMT per lane-mile for the fourth group is greater than 15,000, but the average for the other three is below what could be considered areawide congestion. The average principal arterial street congestion for urban areas in the first, third, and fourth groups could be considered above undesirable levels.

1990 Roadway Congestion Index Estimates

The average congestion levels (as represented by the RCI values) for the four population density groups are shown in Table 38. Urban areas in the fourth group have an average level of congestion 20 percent greater than what might be considered the beginning of areawide congestion (RCI value of 1.20). The other three groups have average congestion levels slightly less than the threshold for average areawide congestion.

Table 38. 1990 Roadway Congestion Index Values Grouped by Population Density

Pop. Density Group	Freeway / Expressway		Principal Arterial Street		Roadway[3] Congestion Index
	DVMT[1] (1000)	DVMT/[2] Ln-Mile	DVMT[1] (1000)	DVMT/[2] Ln-Mile

Roadway Congestion Trends, 1982 to 1990

The average congestion levels from 1982 through 1990 for the four population density groups are presented in Table 39. The urban areas with the highest population density (fourth group) have exhibited the largest increase in congestion at 21 percent. The other three groups have experienced a slower growth in congestion, increasing between 13 and 16 percent between 1982 and 1990. Figure 6 provides a graphical picture of congestion trends for the four groups over the past 8 years.

Table 39. Roadway Congestion Index Values Grouped by Population Density, 1982 to 1990

Pop. Density Group	Year									Percent Change, 1982 to 1990
	1982	1983	1984	1985	1986	1987	1988	1989	1990	
Fourth Group	0.99	1.01	1.04	1.05	1.11	1.13	1.16	1.19	1.20	21
Third Group	0.83	0.85	0.86	0.89	0.92	0.93	0.96	0.96	0.97	16
Second Group	0.81	0.82	0.83	0.85	0.87	0.89	0.89	0.91	0.92	13
First Group	0.81	0.84	0.88	0.89	0.91	0.92	0.93	0.93	0.94	16

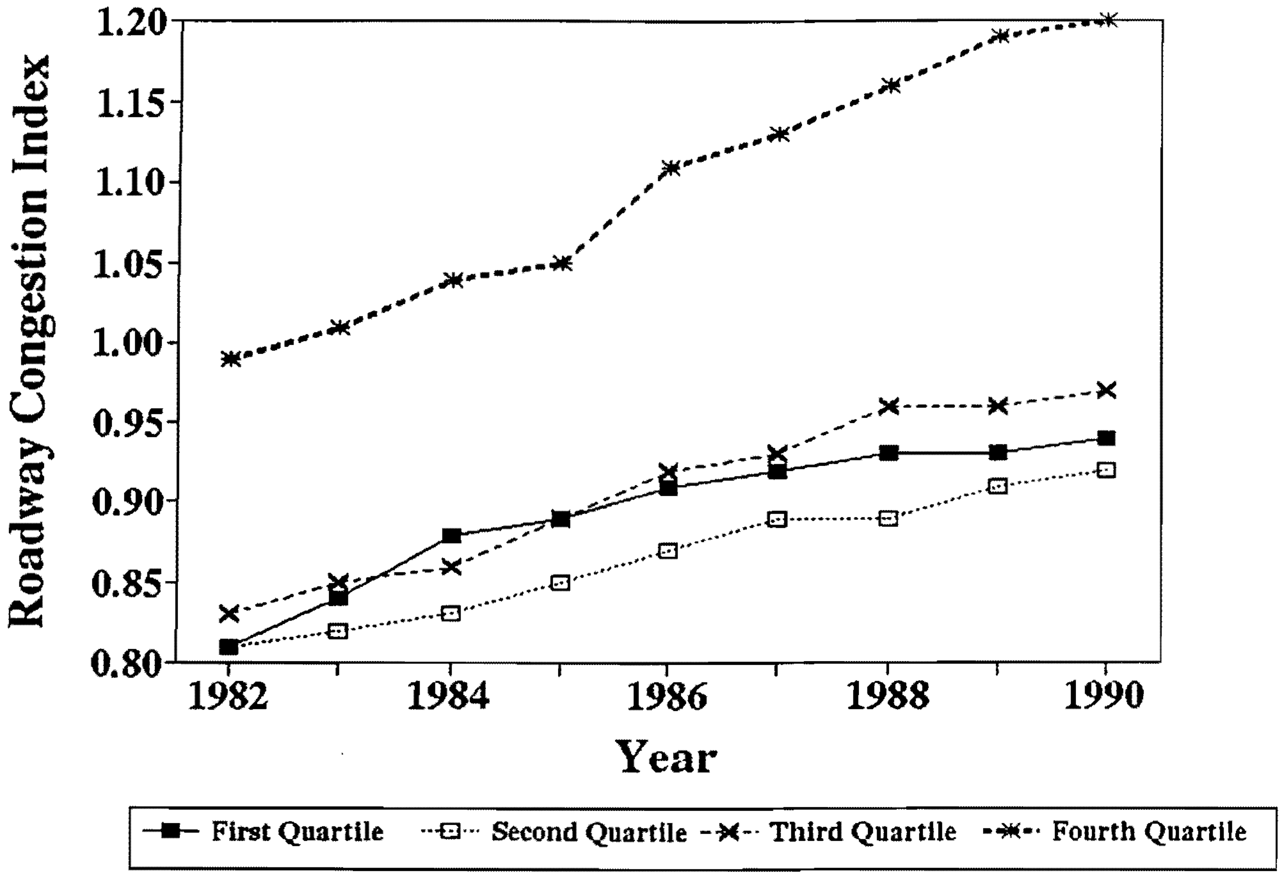

Figure 6. Roadway Congestion Index Values Grouped by Population Density, 1982 to 1990

Travel Delays

Table 40 presents the average delay for the four groups. Again, urban areas in the fourth group of population density experience greater than four times the average amount of total delay as areas in any of the other groups. The total delay per 1000 persons ranges from 110 vehicle-hours for the fourth group to 60 vehicle hours for the second group.

Table 40. Total Vehicle-Hours of Delay for 1990 Grouped by Population Density

Pop. Density Group	Total Delay (vehicle-hours)	Total Delay per 1000 Persons
Fourth Group	536,530	110
Third Group	106,860	70
Second Group	75,230	60
First Group	100,580	70

Source: TTI Analysis

Costs of Congestion

The annual congestion costs for delay and wasted fuel are shown in Table 41. The average total delay and fuel cost for urban areas in the fourth group is $2.32 billion per year, over five times the cost incurred by congestion in any of the other groups. The congestion costs per vehicle range from $750 for the fourth group to $340 for the second group. The cost per capita is slightly lower, ranging from $470 in the fourth group to $250 in the second group. As illustrated earlier, the larger difference in costs per capita and per vehicle in the cities in the fourth group reflects the lower vehicle ownership rates of urban areas with high population density.

Table 41. 1990 Component and Total Congestion Costs Grouped by Population Density

Pop. Density Group	Annual Cost Due to Congestion ($Millions)			Cost per Registered Vehicle ($)	Cost per Capita ($)
	Delay	Fuel	Total		
Fourth Group	1,970	340	2,310	750	470
Third Group	390	70	460	450	310
Second Group	270	40	310	340	250
First Group	380	70	450	430	320

CONCLUSIONS

This research report represents the results of the fifth year analysis of a six-year research effort focused on quantifying urban mobility. Relative mobility levels in 50 urban areas throughout the country were presented and discussed in this report. The 50 urban areas studied include the seven largest in Texas and a representative cross section of other large urban areas.

The Roadway Congestion Index (RCI) is one measure of urban mobility levels. This value is based on daily vehicle-miles of travel per lane-mile of roadway. The RCI values are intended to be areawide rather than site specific representations of congestion level.

The RCI values in Table 6 illustrate the growing congestion problem in medium and large urban areas in the United States. Congestion exceeded desirable levels in 24 areas in 1990, up from 11 in 1982. Only three of the 50 areas, Phoenix, Houston and Detroit, have had decreases in congestion between 1982 and 1990.

In 1982, eleven urban areas had achieved levels of undesirable congestion, by 1986, seven additional areas had reached or surpassed the point at which undesirable levels of congestion occur. This same trend of growth in congestion, continued through 1990 with six additional urban areas reaching a level of undesirable congestion bringing the total number of cities with undesirable levels of congestion to 24.

Ten more urban areas have estimated RCI values ranging between 0.97 and 0.90. These areas may not experience undesirable levels of congestion in the immediate future; however, congestion levels could become undesirable within the next five to ten years.

Houston (tied for 10th) was the only Texas urban area which was included in the ten most congested urban areas. Dallas (tied for 17th) was the second highest ranked area within the state. Austin was the third highest ranked (tied at 30th) urbanized area in the state with the remaining four Texas cities not ranked in the top 30.

The cost of congestion in the 50 urban areas studied exceeded $43.2 billion in 1990. Thirteen areas had costs greater than or equal to $1 billion. These 13 areas accounted for $31.2 billion or about 74 percent of the congestion costs of the 50 urban areas studied. It can be seen in Table 16 that delay, both recurring and incident, accounted for approximately 85 percent of the congestion costs of an urban area, while excess fuel consumption accounts for the remainder. Increases in delay and fuel costs averaged about 11 percent annually between 1987 and 1990. Twenty-seven of the 50 areas had annual increases greater than or equal to 10 percent.

The effects of congestion costs on the individual can be seen by relating cost to population and vehicle ownership. Washington, D.C. has the highest cost per registered vehicle at $1,420, while San Bernardino-Riverside has the highest cost per capita at $880. The average cost per vehicle and cost per capita are $480 and $340, respectively. The average annual growth of both these values was 9 percent between 1987 and 1990 (in unadjusted dollars). Twenty-four areas had cost per vehicle growth rates equal to or greater than 10 percent over the four year period. Twenty-three areas had cost per capita annual growth rates equal to or greater than 10 percent between 1987 and 1990.

There are many different ways to group the urban areas in order to view trend characteristics. One such way is by population. When grouping the study areas by population, it is possible to see the quantity of congestion present in certain general sizes of urban area. Table 31 shows the DVMT, DVMT per lane mile, and RCI value for five population groups. The smallest urban areas, group one, have an average RCI value of 0.89. This shows that these smaller areas, populations less than or equal to 800,000, are approaching the level where areawide congestion is occurring. Group 3, comprised of urban areas whose population is between 1.17 and 1.90 million, has an average RCI value of 1.01. This shows that, on the average, congestion is already occurring in areas of this size.

Differences in the rankings within Table 18 indicate that no single measure of congestion can capture all of the aspects of the congestion issue. Table 8 similarly indicates that the amount of roadway capacity necessary to achieve a constant congestion level is beyond the ability of most medium and large urban areas. While much discussion centers on reducing congestion, it would seem that on an areawide basis, a more realistic goal for the roadway system would be to maintain existing congestion levels.
