15. Supplementary Notes

Study was conducted in cooperation with the U.S. Department of Transportation, Federal Highway Administration. Research Study Title: Improving Transportation Planning Techniques.

16. Abstract

This document provides the Texas Department of Transportation the initial step in developing a methodology for conducting intercity route studies. It is intended to assist the analyst in identifying the key factors that should be addressed in intercity route studies and to provide guidance in selecting the appropriate procedure(s) for evaluating these factors. In many cases the procedures presented have not been extensively tested and should be used with caution; in some cases, the procedures are either overly simplistic, in the development stage, or non-existent. Therefore, numerous "gaps" and caveats exist; recommendations for filling these gaps are enumerated wherever appropriate.

The Guide consists of five chapters, four of which correspond to the four-step framework recommended for conducting intercity route studies. Several appendices provide guidelines concerning origin-destination studies, recommended data sources, descriptions of alternative methodologies, and additional documentation for selected topics which are treated in less detail in the main text.

ABSTRACT

This document provides the Texas State Department of Highways and Public Transportation is the initial step in developing a methodology for conducting intercity route studies. It is intended to assist the analyst in identifying the key factors that should be addressed in intercity route studies and to provide guidance in selecting the appropriate procedure(s) for evaluating these factors. In many cases the procedures presented have not been extensively tested and should be used with caution; in some cases, the procedures are either overly simplistic, in the development stage, or non-existent. Therefore, numerous "gaps" and caveats exist; recommendations for filling these gaps are enumerated wherever appropriate.

The Guide consists of five chapters, four of which correspond to the four-step framework recommended for conducting intercity route studies. Several appendices provide guidelines concerning origin-destination studies, recommended data sources, descriptions of alternative methodologies, and additional documentation for selected topics which are treated in less detail in the main text.

DISCLAIMER

The contents of this report reflect the views of the authors who are responsible for the opinions, findings, and conclusions presented herein. The contents do not necessarily reflect the official views or policies of the Federal Highway Administration or the State Department of Highways and Public Transportation. This report does not constitute a standard, specification, or regulation.

EXECUTIVE SUMMARY

BACKGROUND

The Transportation Systems Planning Subsection of the Transportation Planning Division (D-10P) is responsible for conducting intercity route studies.[1] In the past, these studies have been conducted on an "as needed" basis in response to requests brought before the State Highway Commission or in response to directives received from the SDHPT Administration. The reasons most frequently cited to justify new or improved intercity highways are the need to achieve improved traffic movement and/or the need to promote economic development. A great deal of staff time and money have been consumed in responding to these specific, individual requests for intercity route studies.

The Department is currently developing a State Highway Trunk System Plan, and intercity route planning is becoming more system-oriented. As a result, there is a need for the Department to expand and refine its current basic methodological framework for conducting intercity route studies. A standardized methodology which is sensitive to traffic, economic development, and system connectivity is needed. This Guide represents an initial step in the development of such a methodology.

PURPOSE AND ORGANIZATION OF THIS GUIDE

This document is intended to provide the Department with guidelines for conducting intercity route studies. This Guide is intended to assist the analyst in identifying the key factors that should be addressed in intercity route studies and to provide guidance in selecting the appropriate procedure(s) for evaluating these factors. The use of this Guide, however, must include an intelligent application of judgment and experience. This Guide is designed to assist the analyst in conducting intercity route studies but cannot replace the important role of professional judgment in designing and conducting traffic studies.

---

[1]The Department distinguishes between two types of intercity route studies: (1) route studies (new facilities/new alignment), and (2) feasibility studies (upgrading an existing facility). In this guide, the phrase "intercity route studies" will be used to refer to both of these types of studies.

It must be emphasized that this Guide is only an initial step in developing a standardized methodology for conducting intercity route studies. In many cases, the procedures presented in this document have not been extensively tested and should be used with caution. In some cases, the procedures are either overly simplistic, in the development stage, or non-existent. Therefore, the reader will find numerous "gaps" and caveats in this document. Recommendations for filling these gaps are enumerated wherever appropriate. This document is intended to provide an initial framework for the development of a more comprehensive intercity route study guide over the coming years.

This Guide consists of five chapters, four of which correspond to the four-step framework recommended for conducting intercity route studies. In addition, Chapter V provides some preliminary guidelines concerning the planning and operation of bypass routes. Chapter IV offers guidelines for preparing intercity route study reports. Several appendices provide guidelines concerning origin-destination studies, recommended data sources, descriptions of alternative methodologies, and additional documentation for selected topics which are treated in less detail in the main text.

In subsequent versions of this Guide, the mathematical procedures and models will be presented in the following general format:

(1) Overview of the procedure;

(2) Basis for the development of the procedure;

(3) Data requirements;

(4) Features and limitations of the procedure; and

(5) An example application.

In those areas where no procedural modifications or refinements in current Department practice were deemed necessary, the guidelines and methodologies presented in this Guide simply document these practices and are so noted. Any recommended new procedures, and/or modification of current Department practices are also identified.

I. STUDY DESIGN AND INVENTORY OF CURRENT CONDITIONS

STUDY DESIGN

Because the effectiveness of planning depends very much upon the existence of a good data base and sound analytic methods, designing a data collection, data analysis, and project management plan is an important initial task in all planning activities. This plan, or study design, should identify data requirements, specify data analysis procedures, provide a work completion schedule, and assign agency responsibilities with regard to these and other relevant aspects of the study.

The development of the study design for intercity route studies should commence with an initial planning meeting involving representatives of the Department divisions and districts that will be participating in the study. The objective of this meeting should be to identify and assign responsibilities for the following aspects of the study:

(1) Study area boundaries;

(2) Data requirements, data sources, and data collection procedures;

(3) Data analysis procedures; and

(4) Work completion schedule.

The scope of individual intercity route studies, and the level of detail required by their respective study designs, will, of course, vary depending upon whether the route in question is a new facility on a new alignment or an improvement in an existing facility. In either case, the importance of developing a study design which will insure an efficient and timely completion of the problem under investigation cannot be overemphasized.

The following section of this chapter provides guidelines concerning the basic data requirements for intercity route studies. Guidelines concerning data analysis procedures are provided in subsequent chapters of the Guide.

INVENTORY OF CURRENT CONDITIONS

A number of factors can influence the demand for, and feasibility of, intercity highway improvements. The identification and quantification of these factors provides the basis for developing the study design and, to a large extent, defines the nature of the analytic methods which can be employed in subsequent phases of the study. The initial

inventory of current conditions in the study corridor should focus on determining the availability of, or feasibility of obtaining, the following basic information.

A. Traffic/Transportation System Data

(1) Inventory of existing highway facilities in the study corridor (functional class, cross sections, etc.).

(2) Proposed and programmed roadway and traffic operations improvements in the study corridor.

(3) Historical traffic volume trends on the roadways in the study corridor. The availability of data concerning ADT, peak/design hour traffic, turning movements, vehicle classifications, and vehicle occupancy rates should also be investigated. The volume of traffic, both present and projected, is an important factor in determining the need for highway improvements.

(4) Corridor travel patterns. Depending upon the scale of a particular intercity route study, data on the number of trips (vehicles and persons) between the major origins and destinations in the study corridor may be required. In the absence of existing data, or procedures for synthesizing origin-destination (O-D) data, O-D surveys may need to be conducted at critical points on the highways in the study corridor. Appendix A provides detailed guidelines for conducting O-D studies.

(5) Current level of service provided by roadways in the study corridor.

(6) Historical and current traffic accident data for the roadways in the study corridor. Highway safety is a major consideration in establishing a highway project's priority. Accident rates are typically calculated on the basis of accidents per 100 million vehicle-miles of travel. The accident rate for a particular roadway can be compared with the statewide average for the same type of highway facility to determine whether a disproportionate number of accidents have occurred on the roadway in question.

B. Demographic and Land Use Data

(1) Population trends. The location of intercity highways in relation to population centers affects both the nature and magnitude of the traffic on the facility.

(2) Land uses and economic activity (existing and proposed). The type of

highway facility needed to serve a particular area is largely a function of land use. Land use information is needed to identify traffic generators, and to assess the access requirements of intercity highway facilities. In addition, land use information is needed to estimate the cost of purchasing any additional right-of-way which may be required. Finally, the land use inventory identifies special and/or environmentally sensitive areas (parks, wildlife refuges, wetlands, churches, cemeteries, historical, recreational, and scenic sites) that can affect route alignment considerations.

DATA SOURCES

The primary source for traffic and transportation system data is the Road Inventory and Traffic Log (TLOG) maintained by D-10. This Log provides historical and current traffic information for the existing State and Federal-Aid Highway Systems as well as projected design year ADT and other design data for this highway network. (The procedures used to project the design year traffic are described in Chapter II of this Guide).

For each control-section on the State Highway System, the 20-year design data in the TLOG are developed from traffic information obtained at permanent automatic traffic recorders, from manual classification counts, and from truck weight studies. The data include the K factor, directional distribution factor, percent trucks in both ADT and the design hour volume (DHV), the average of the 10 heaviest wheel loads daily (ATHWLD), the percent of tandem axles in this average, and a structural design pavement analysis for flexible and rigid pavements. A sample listing of one subset of the information in the TLOG is shown on the following pages. (See Appendix B for definitions of the abbreviations used in the TLOG). Other TLOG data sets contain physical descriptions and accident data for the highways on the State Highway System.

Information concerning programmed roadway improvements can be found in the Department's Project Development Plan (PDP).

Table 1 presents the level of service threshold volumes used by the Department to assess the adequacy of individual roadway segments on the State Highway System. These values should be used to evaluate the current level of service provided by roadways in the study corridor.

Sources of historical and projected population for Texas include the Texas State Data Center (TSDC, Texas A&M University), Bureau of Business Research (BBR), Texas Department of Health (TDH), Texas Department of Water Resources (TDWR), U.S. Bureau of the Census (BC), National Planning Association (NPA), Woods and Poole (WP), and the Governor's Office. Of these agencies, TSDC, NPA, TDH, TDWR, and WP make projections by counties. Further, TDH and BBR make annual projections of state-wide population, while TDWR and NPA make only five-year projections. The BC and WP make 10-year population projections. Appendix C contains county-level population and economic data (current and projected) which should be used in intercity highway studies.

The current land-use information needed for intercity route studies should be obtained through field surveys. The analyst should also contact local planning and economic development agencies and SDHPT district office personnel to obtain information concerning current and proposed land uses in the study corridor.

[a]A "divided" facility includes a flush or depressed median with sufficient width for storage of left turning vehicles. On "undivided" facilities, left turns are made from a through lane.

[b]"Urban street", as opposed to "rural highway," conditions prevail whenever the intensity of roadside development, speed zoning, signals, stop/yield signs, etc., result in interrupted flow conditions and reduced traffic speeds.

[c]Used as limiting value for tolerable flow for all two-lane roadways (urban and rural operation) in 10-Year Project Development Plan except for rural rolling terrain.

II. FORECASTING FUTURE CORRIDOR TRAFFIC

Unlike the advanced, relatively sophisticated computer modeling programs used for urban traffic forecasting, procedures for forecasting traffic on rural highways are relatively simplistic. These procedures typically involve determining a simple trend using historical data and may vary only in terms of whether a simple or compounded growth rate is used.

The procedures presented in this Chapter are intended to assist the analyst in forecasting the general magnitude of future rural traffic volumes. Preliminary procedures for adjusting these basic forecasts to account for changes in land use, certain demographic factors, and the traffic diversion potentials of new or improved intercity highway facilities are also presented. These procedures, when combined with the intelligent application of judgment and experience, should result in reasonably accurate forecasts of future traffic.

Given the relatively slow, uniform traffic growth rates experienced on most rural highways where traffic volumes are generally low enough that modest errors in forecasting are not likely to substantially alter basic design decisions, these simple procedures are entirely appropriate, in terms of their level of accuracy, for most intercity highway planning studies.

ESTIMATING AND FORECASTING INTERCITY TRAFFIC VOLUMES

The current procedures used by the Department to estimate and forecast intercity highway traffic volumes are essentially manual procedures which rely heavily on historical trends observed in counted traffic volumes. Intercity traffic volumes are currently estimated on the basis of the "lowest ADT" on a particular roadway. The reasoning implicit in this approach is that intercity traffic on a particular roadway cannot be more than the lowest ADT on that roadway. Regression models developed from historical traffic data are used to forecast future intercity traffic volumes. While this "lowest ADT" includes local as well as intercity traffic, it probably represents a reasonably accurate planning level estimate of intercity traffic volume.

This "minimum ADT" approach has been challenged on the basis that it is overly simplistic in as much as it does not segregate the local and intercity components of ADT and does not explicitly account for the various socio-demographic variables which can effect

current and future intercity traffic volumes. However, until more refined procedures can be developed, and in those situations where O-D data for the corridor in question are not available, the analyst should continue to use this "minimum ADT" approach to estimate intercity traffic volumes[2]. Procedures for developing forecasts of future intercity traffic volumes are outlined below.

TRENDLINE FORECASTING PROCEDURES

Perhaps the most commonly used rural traffic forecasting procedure is trendline analysis. This type of analysis uses historical traffic trends to develop an estimate of annual growth which is likely to occur in the future. Typically, trendline analysis is used to develop traffic forecasts for rural highways which are not part of computerized networks.

The annual growth rates used in trendline analysis are determined by examining a plot of the historical traffic data, by using simple linear regression analyses to fit a line through the data, or by simply choosing two data points which define the most appropriate trend and calculating an average growth rate. The growth rate, expressed as an average percentage, is found through the use of the following equation:

$$\text{Average Percentage Growth} = ((X_2 - X_1/X_1N) \times 100\%$$

where:

X_2 = Final data point

X_1 = Initial data point

N = Number of years between X_1 and X_2

The resulting growth rate is then multiplied by the number of years between the most recent data point and the forecast year. This total anticipated percentage growth is then multiplied by the value of the initial data point to yield the anticipated increase or decrease. By adding the anticipated growth to the initial data value, the forecast value can be

[2] A number of alternative procedures for estimating and forecasting intercity travel demands have been proposed. These range from the use of a simple gravity model to the development of computerized, network-based travel demand models (1,2). Any such procedures that might be developed will be incorporated into future versions of this guide.

obtained. This process is summarized in the following equation:

$$\text{Forecast Value} = [(AGP)(N_1)(X_1)] + X_1$$

where:

AGP = Average percentage growth

N_1 = Number of years between initial year and forecast year

X_1 = Initial data value

It should be noted that this growth rate is linear, with a constant amount of growth assumed each year. Such a forecast might be most appropriate in a region which can support only a finite annual amount of growth. As an example, if a region's real estate market could absorb only X number of housing or office units per year, but growth at this rate could be maintained during the entire forecast period, this type of trend analysis could be very appropriate.

If the historical data indicate a nonlinear growth rate, a forecast based on a compound percentage growth may be more appropriate. The compound growth rate is calculated with the following equation:

$$\text{Compound Growth Rate} = (X_2/X_1)^{1/N} - 1$$

where:

X_2 = Final data point

X_1 = Initial data point

N = Number of years between X_1 and X_2

The resulting compound growth rate is used to forecast future traffic through use of the following equation:

$$\text{Forecast Value} = (X_2)(1 + ACG)^{N1}$$

where:

X_2 = Most recent data value

ACG = Average compound growth rate

N_1 = Number of years between the most recent data observation and the forecast year

Caution should be used in applying compound growth rates to long forecast periods,

as compounding results in progressively larger increases in growth each succeeding year. This is illustrated in Figure 1, which shows the difference in growth factors for an average annual growth rate and a compound growth rate for an assumed annual growth rate of 10 percent. The use of a combination of linear and compound growth rates may be appropriate for some long range forecasts. The Florida DOT, for example, uses a compound growth rate for the first 10 years of the forecast and a linear growth rate thereafter. While this guideline should not be taken as a hard-and-fast rule, it points out the need for the analyst to employ professional judgment to assess the reasonableness of long-term traffic forecasts.

The design year (20-year) traffic forecasts in the TLOG were developed using growth factors developed from one of the following methods: (1) site-specific growth rates based

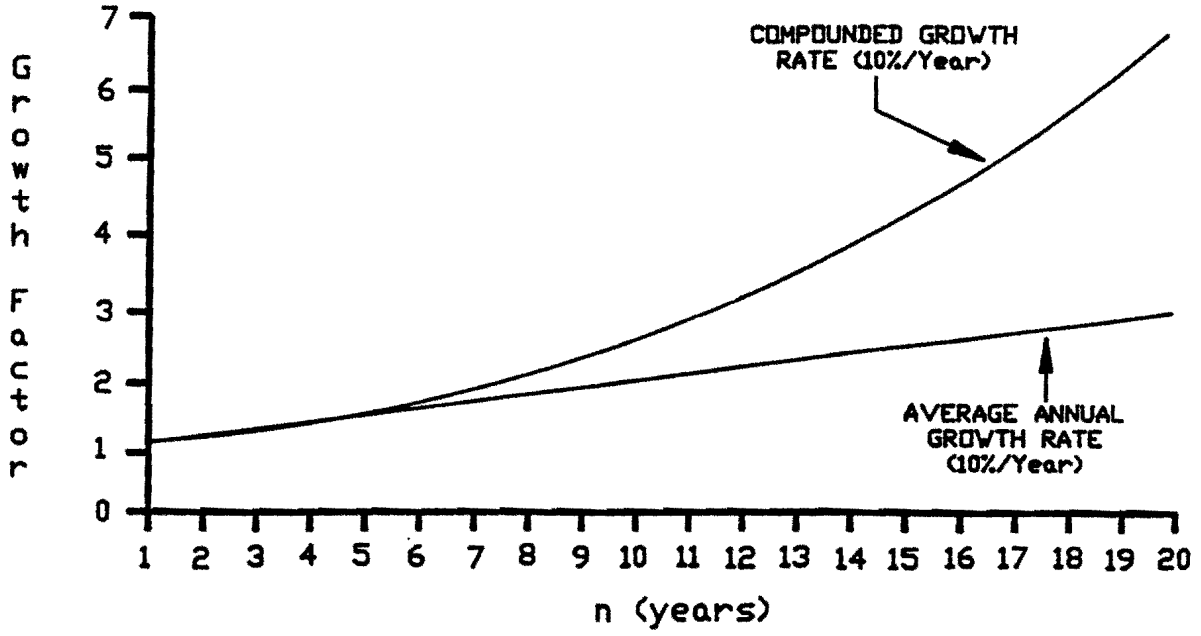

Figure 1. Comparison of Average Annual and Compounded Growth Rates.

on regression analysis of traffic volume trends over the past 10 years; or (2) county-wide average traffic growth rates based on analysis of traffic volume trends over the past 10 years (this approach is used if the "scatter" in the historical data is too wide for regression analysis). The regression model is of the form:

$$Y = \beta_0 + \beta_1 X$$

where:

Y	=	ADT
β_0 β_1	=	regression coefficients
X	=	Traffic year (0 = current year, ..., 9 = 9 years prior to current year)

The historical traffic data in the TLOG have been used to estimate the model coefficients (β_0 and β_1). For those estimates which were statistically significant, the resulting regression models were used to develop the forecasts of future (design year) traffic contained in the TLOG.

DEMOGRAPHIC-BASED FORECASTING PROCEDURES

Traffic growth factors based on historical traffic data inherently capture the combined effects that population changes, economic activity, and other factors have on traffic growth rates. The use of traffic trending methods to forecast future traffic volumes assumes that the growth rates and relationships reflected in the historical traffic data will remain constant through the forecast year. If population and/or employment, for example, are projected to grow at a rate different than observed in the past, the trendline traffic forecasts should be modified to account for these differences.

The feasibility of developing demographic/elasticity-based forecasting models for the Department is currently being evaluated. If appropriate, these models will be incorporated into subsequent versions of this Guide. In the meantime, the simple approach outlined below can be used to adjust trendline traffic volume forecasts to account for population and employment growth rates which differ from historical growth rates. The economic and demographic data and forecasts in Appendix C should be used when making adjustments to the basic trendline forecasts.

Table 2 summarizes historical traffic data from two permanent traffic recorder

stations along I-35 between Austin and San Antonio. Also shown in the table are the corresponding year 2000 traffic forecasts for the two sites. The forecasts were developed using the linear regression model presented in the description of the TLOG in the preceding section of this chapter. These forecasts represent a simple linear trending of the historical traffic data. The assumption implicit in trendline forecasts is that past trends (including population growth) will continue unchanged into the future. To validate this assumption, the analyst should compare historical and projected population data.

Table 3 shows historical population data for countries in the I-35 corridor between Austin and San Antonio for the period 1970-1980. As shown in the table, total corridor population grew by 2.9 percent per year during this time period. The corresponding 2000 county population forecasts are shown in Table 4. A comparison of the data in Tables 3 and 4 shows that the historical and projected growth rates for total corridor population are essentially equal (2.9 percent for the period 1970 to 1980 vs. 2.7-3.3 percent for the period 1980-2000).

Table 2. Historical and Projected Traffic Volumes (ADT), I-35

Year	New Braunfels Station	Kyle Station
1970	16,100	14,700
1971	18,600	16,400
1972	19,100	18,400
1973	21,700	20,500
1974	20,700	19,100
1975	21,600	20,600
1976	23,800	21,200
1977	24,500	22,700
1978	25,600	24,800
1979	25,800	24,100
1980	24,000	23,000
2000	55,500	64,900

Source: D-10P, SDHPT.

In this case, the assumption that future population will follow historical trends appears to be valid. Therefore, at the corridor level it is not necessary to adjust the traffic volume forecasts to account for population growth.

While in this example it does not appear to be necessary to adjust the trendline traffic forecasts to account for population growth at the corridor level, some adjustments at the county level may be warranted. For example, population in Hays County grew at a rate of 6.00 percent per year between 1970 and 1980 (Table 3). The 2000 projections, however,

indicate a growth rate of only 1.8-3.6 percent (Table 4). In this case, the analyst should give consideration to adjusting the traffic forecasts to account for this projected decline in the county's population growth rate. A simple factoring process, based on the ratio of projected to historical population growth rates, can be used. The basic approach is summarized in the following equation:

$$ADT2 = ADT1 (PPGR/HPGR)$$

where:

ADT2 = Adjusted traffic forecast

ADT1 = Trendline traffic forecast

PPGR = Projected population growth rate

HPGR = Historical population growth rate

This approach can be extended to include other socioeconomic factors (such as employment) as shown below:

$$ADT2 = ADT1 (PPGR/HPGR \times PEGR/HEGR \times ...)$$

where:

PEGR = Projected employment growth rate

HEGR = Historical employment growth rate

A shortcoming of the simple factoring procedure outlined above is that it assumes a constant, one-to-one relationship between changes in traffic volume and other factors (e.g., population and employment growth). There is considerable evidence that the relationship between travel demand and certain socioeconomic factors is "elastic" (i.e., a 1 percent change in certain demographic factors produces a greater than 1 percent change in travel demand). For example, preliminary analyses of historical traffic and population trends in the I-35 corridor (see Tables 2 and 3) indicate that for every 1 percent increase in corridor population, traffic on I-35 increased by 2.5 percent. This elasticity can be used to adjust trendline forecasts using the following equation[3]:

[3] The analyses are documented in (3).

Table 4. Historical and Projected County Populations, I-35 Corridor

County	Population by Year and Source		
	1980 Census	2000	
		Texas Department of Water Resources	Texas Department of Health
Bastrop	24,700	47,000 (3.3%)[a]	59,100 (4.5%)
Bexar	988,800	1,484,200 (2.1%)	1,570,300 (2.3%)
Caldwell	23,600	30,300 (1.3%)	38,200 (2.4%)
Comal	36,400	66,800 (3.1%)	85,200 (4.3%)
Guadalupe	40,600	71,100 (3.0%)	97,100 (4.7%)
Hays	46,700	90,900 (3.6%)	65,200 (1.8%)
Travis	419,600	760,900 (3.1%)	819,700 (3.2%)
Williamson	76,500	201,600 (5.0%)	310,600 (7.3%)
Total	1,656,900	2,752,800 (2.7%)	3,045,400 (3.3%)

[a](X.X%) denotes compound annual growth rate since 1980.

$$ADT2 = ADT1\ [1 + 0.025\ (\%\ \text{change in PGR})]$$

where:

% Change in PGR = % change in projected and historical population growth rates.

This elasticity equation was estimated using data from only one rural interstate highway corridor which experienced population growth. The equation should not be used for non-interstate highways or in other interstate highway corridors which have not experienced population growth. The recommended application of this elasticity equation is in conjunction with the simple factoring procedure presented in the previous paragraphs to develop a range of ADT forecasts.

In applying the methods presented in this section, the analyst will need to rely upon professional judgment to determine the geographic area (urban area, county, corridor, etc.) that will be effected by the project. The construction of a major new roadway, for example, can have regional impacts and the analysis should be conducted at that level. For site-specific projects, the impacts will be more localized, and the analyses should be conducted at the urban area or county level.

ADJUSTMENTS FOR PROPOSED LAND USES

Just as the analyst should review trendline forecasts in terms of historical and projected demographic factors in the study corridor, the extent to which traffic forecasts capture the effects of new land uses in the corridor should also be evaluated. Because traffic forecasts based on historical trends implicitly assume that these past trends, including land development trends, will continue into the future, the analyst must assess the extent to which the proposed land-use change in question differs from the types of developments which have occurred in the corridor in the past. If the proposed land use is "typical" of past development patterns in the corridor, then the trendline forecasts probably represent to some extent the effects of the proposed development. If, on the other hand, the proposed land use differs substantially from past patterns in terms of its magnitude or nature, then the traffic forecasts will need to be adjusted accordingly. No hard-and-fast guidelines concerning the need for these adjustments can be offered, and the analyst must rely upon personal knowledge of the study area and professional judgment to resolve this issue.

If the analyst determines that the trendline forecasts need to be adjusted to account for proposed land uses, the procedure outlined in Appendix D should be followed to determine the appropriate adjustments.

ADJUSTMENTS FOR DIVERTED TRAFFIC

The construction of a new roadway, or a major upgrading of an existing roadway, can significantly alter travel patterns and traffic volumes in a corridor. The analyst should consider the shift (diversion) of traffic between facilities that can result from the construction of new roadways or from the major reconstruction of an existing roadway.

A literature review identified the following six non-network-based traffic diversion procedures (4, 5, 6):

(1) AASHTO diversion curves;

(2) California time and distance diversion curves;

(3) Ratio diversion procedure (referred to in (4) as the "easy" method);

(4) All-or-nothing diversion;

(5) Bureau of Public Roads (BPR) diversion curve; and

(6) Dial's probabilistic diversion procedure.

Of these six procedures, only procedures (1) through (4) appear to have been tested against actual survey data to determine their relative accuracy. As a result, only these four procedures are described in detail in this section of the Guide. The following description of these four traffic diversion procedures comes from (4). The BPR diversion curve and Dial's probabilistic diversion procedure are outlined in Appendix E.

It should be stressed that none of these procedures have been tested in Texas. Moreover, the use of these procedures requires knowledge of the number of trips between the major origins and destinations in the study corridor. In the absence of O-D data for the study corridor, or procedures for synthesizing these data, the lowest ADT on a particular highway can be used as a preliminary estimate of intercity traffic volumes. It is recommended that two or more of these procedures be used to develop a range of estimates of the traffic diversion potentials of intercity highway improvements.

(1) AASHTO Diversion Curve.

$$\text{Percent Use} = 1/(1 + T^6)$$

Where T is the ratio of the travel time via the facility under study to the time via the best alternate route. (Note: distances can be substituted for time in this equation.)

(2) California Time and Distance Curves.

$$\text{Percent Use} = 50 + [[50(d + 0.5t)]/[(d - 0.5t)^2 + 4.5]^{0.5}]$$

Where "d" is the distance saved by the route under study compared to the best alternate, and "t" is the time saved by the route under study versus the time for the best alternate route. Both "d" and "t" may be negative. When the percentage of use is calculated using the time differential of the best alternate, the distances associated with the same minimum alternate paths should be employed to obtain "d." This is necessary because the time and distance paths frequently do not coincide for either the minimum or best alternate path.

(3) The "Easy" Method.

$$\text{Percent Use} = 50 + 250[(B - A)/(B + A)]$$

Where "A" is the travel time via the route under study and "B" is the travel time via the alternate route. It is recommended that the percentage of use be set at 0 if (B - A)/(B + A) is less than -0.2, and at 100 if this quantity exceeds +0.2.

(4) All-Or-Nothing Technique.

In this technique, all trips are assigned to the path that provides the minimum absolute time or distance between origin and destination, and no trips are assigned to the alternate route.

Table 5 presents a comparison of these four traffic diversion techniques in terms of their ability to replicate observed traffic distributions. The data in Table 5 are from a 1968 study that compared estimated and observed volumes before and after the installation of a major river crossing in rural Connecticut (4). As shown in the table, all four diversion techniques performed reasonably well providing diversion estimates which ranged from 90 to 119 percent of the survey volumes. The AASHTO method (using time as the parameter) exhibited the lowest standard error, though the results of the California method best matched the aggregate survey data.

Based on this rather limited data, it is recommended that the analyst use the AASHTO and the California techniques to estimate the traffic diversion potentials of intercity highway projects in Texas. The traffic forecasting procedures described in previous sections of this Guide can be used to develop forecasts of future traffic on the highways in question.

Table 5. Comparison of Traffic Diversion Techniques, Connecticut River Bridge Study (1968)

Bridge	Parameter	Traffic Distribution (Veh./Day)											
		Survey	AASHTO			California			Easy			All-or-None		
			No.	%[a]	Std. Error	No.	%	Std. Error	No.	%	Std. Error	No.	%	Std. Error
South	Time	10,222	9,647	94	42.3	10,659	104	64.8	9,646	94	45.8	12,186	119	149.2
	Dist.		9,243	90	51.3	10,649	104	64.1	9,306	91	49.2	10,859	106	99.9
North	Time	5,717	6,292	110	--[b]	5,280	92	--	6,293	110	--	3,753	66	--
	Dist.		6,696	117	--	5,290	93	--	6,633	116	--	5,080	89	--

III. PROJECT EVALUATION

LEVEL OF SERVICE ANALYSIS

The traffic forecasts developed using the procedures described in Chapter II provide the basis for assessing the adequacy of existing and proposed highway facilities in the study corridor to accommodate the anticipated future traffic volumes. The level of service threshold values presented in Chapter I should be used to perform the level of service analysis (See Table 1).

The level of service analyses should be performed on the existing highway network (i.e., without the proposed improvement(s)) as well as on the proposed network(s) (i.e., with the proposed improvement(s)). Assessing the adequacy of the existing network to accommodate the projected (design year) traffic volumes provides an indication of the magnitude of any improvements that might be needed in the study corridor.

To the extent it is feasible, the level of service analysis should also reflect the effects of Department policies concerning access control/restriction to intercity highways and bypass routes. Guidelines concerning access control will be provided in subsequent versions of this Guide. These guidelines will be based on the findings and recommendations of the Department's Trunk System Task Force.

COST-EFFECTIVENESS INDICES

In assessing the need for new or upgraded intercity highways, the Department considers the following factors: traffic volumes, level of service, population trends, land use, economic development, and safety. While factors other than traffic are considered (e.g., population, land use, and economic development), they are not incorporated directly into the final project evaluation process. For example, previous intercity highway study documents prepared by the Department typically include a summary of historical and projected population in the study corridor, an inventory of significant/sensitive land uses, and a brief discussion of the potential linkages between highway investments and economic development. In the final analysis, however, the feasibility of intercity highway projects is assessed on the basis of cost per vehicle-mile traveled. The specific cost-effectiveness indices used by the Department vary by project type, as described below.

Capacity Increase Projects

Capacity increase projects typically involve widening the cross-section of an existing highway. These projects are evaluated on the basis of the Congestion Relief Index (CRI). This method is based on the current (base year) ADT and is calculated by dividing total project cost (construction and right-of-way) by existing traffic in excess of level of service C-D plus latent traffic demand times the length of the project, as shown below:

CRI = [Construction + Right-of-Way Costs]/[(Existing Traffic > Level C-D + Latent Demand)(Length)]

The level of service threshold volumes used by the Department in these analyses are those presented in Table 1. The latent demand term in the denominator is calculated from the following equation. This equation was estimated by using the Department's existing urban traffic assignment models to calculate the additional traffic volume that would result from various added capacity scenarios.

LD = 5 + 0.126(VOL1) + 3170(VC1) + 3945(FWY) + 0.231(CDIF) - 0.177(CAP2)

where:

LD	=	latent demand
VOL1	=	base year traffic (ADT)
VC1	=	base year volume/capacity ratio
FWY	=	facility type (1 = freeway, 0 = non-freeway)
CDIF	=	increase in capacity (ADT)
CAP2	=	roadway capacity after improvement

New Location Projects

New location projects are evaluated on a cost per vehicle-mile (C/VM) basis. This method is based on base year traffic and is calculated by dividing total project cost (construction and right of way) by the existing traffic times the length of the project, as shown below:

C/VM = (Construction + Right of Way Costs)/[(Existing Traffic)(Length)]

The Department uses a threshold value of $400/vehicle-mile for identifying cost

effective new location projects.

New Loop and Bypass Projects

These projects are evaluated on the basis of cost/vehicle-mile (C/VM_L), with an adjustment for truck traffic (2.4 passenger cars/truck), as shown below:

C/VM_L = (Construction + Right-of-Way Costs)/[(Existing Traffic + Truck Equiv.)(Length)]

The Department currently uses a threshold value of $600/vehicle-mile to identify cost effective bypass route projects.

Principal Arterial System Gap Projects

These projects are intended to add missing or needed links in the state's principal arterial system. Arterial system gap projects are evaluated on a cost/vehicle-mile basis using the same equation as new location projects. The Department uses a threshold value of $350/vehicle-mile to identify cost effective arterial system projects.

ECONOMIC EVALUATION MODELS

In addition to the cost-effectiveness indices described above, the Department also utilizes the Highway Economic Evaluation Model (HEEM)(9) to calculate benefit-cost ratios for proposed highway improvements. The HEEM uses data on values of time, vehicle operating costs, accident costs, construction and right-of-way costs, auto and truck traffic volumes, and type of existing and proposed highway facilities in calculating the benefit-cost ratios.

Another economic evaluation model which is currently being evaluated for possible use in Texas is the Regional Economic Impact Model for Highway Systems (REIMHS)(10). In addition to the basic factors considered in the HEEM, the REIMHS provides an estimate of the employment impacts associated with expenditures for highway improvements. This model can be useful in estimating the economic development impacts of intercity highway improvement projects. The results of the evaluation of the REIMHS model will be incorporated into future versions of this Guide, if the model is found to be a useful and appropriate one for use in Texas.

IV. PREPARING THE PROJECT REPORT

The following are suggested guidelines for preparing intercity route study reports. While the contents of individual reports will vary depending upon the nature of specific studies, several general principles should be followed in all intercity route study reports prepared by the Department. The primary purpose of the project report is to effectively document the basic study tasks and the conclusions reached as a result of these tasks. The report should be clear, brief and direct, and easily understood by all who will be asked to review and/or act upon the results of the study.

The body of the report should not be cluttered with voluminous data listings which are not essential to an understanding of the study's basic conclusions. If data cannot be displayed on a one-or two-page table or figure, they should be placed in an appendix.

In most cases, the essential product of the study will be recommended courses of action. Each alternative that was considered should be summarized in terms of its relative merits and deficiencies in sufficient detail to document the selection of the best alternative.

Figures, such as maps, are more easily understood than long tables. The number and type of figures will vary between studies; however, as a minimum, the following figures should be included in all project reports: (1) project location map, (2) traffic volume and level of service maps, and (3) programmed and/or recommended improvements maps. These figures should be prepared on a Color Graphic Station.

The following basic outline is recommended for preparing intercity route study reports. Adoption of this outline will result in a standard format for subsequent intercity highway route study reports.

(1) Executive Summary. The summary should be brief and conclude with a simple statement of the study's conclusions and recommendations. The Executive Summary should provide the Administration and the Commission with the information needed to make a decision concerning the feasibility of the project in question.

(2) Table of Contents. The table of contents should list the major headings of the study document and identify the page numbers on which these begin. When tables and figures and maps are used, a list of tables and list of figures

should follow the table of contents.

(3) Introduction and Background. The initial chapter of the report should provide a brief overview of the need for the study, its purpose and scope, a summary of previous studies which are relevant to the current investigation, and a brief description of the study corridor. Elements which should be included in this chapter of the report include the following:

(a) *Authorization.* This could be a brief summary of the Commission hearing transcript, minute order, resolution, etc., that authorized the Department to conduct the study in question.

(b) *Purpose and Scope.* This should be in the form of a clear concise statement of the purpose and scope of the study. The scope of the study will typically include economic characteristics, population trends, land uses, traffic volumes, travel patterns, traffic safety, and proposed/planned improvements in the corridor.

(c) *Previous Studies.* This section should briefly summarize the findings of any previous studies that are pertinent to the current study.

(4) Current Conditions in the Study Corridor. This chapter should provide a profile of current conditions in the study corridor. The traffic/transportation and demographic/land-use data which should be addressed in this chapter are enumerated in Chapter I of this Guide.

(5) Future Corridor Traffic. This chapter should summarize the projected design year traffic and level of service on the current and proposed highways in the study corridor. The procedures used to develop these forecasts, including any adjustments to account for land-use changes, traffic diversion, etc., should be described in sufficient detail to permit the reader to assess the reasonableness of these forecasts.

(6) Project Evaluation. The alternatives considered, the procedures used to evaluate these, and the results of the evaluation should be summarized in this chapter. This chapter should summarize the relative merits of the alternatives considered and clearly demonstrate the basis for selecting the best alternative.

(7) Conclusions and Recommendations. Each conclusion drawn from the study

should be set forth in a separate paragraph in concise and direct language. The recommendations resulting from the study conclusions should be presented in a similar manner. The recommendations should respond to the basic objectives of the study effort as set forth in the "Purpose and Scope Section" of the study report. In most cases, recommendations should be worded to indicate specific actions to be taken.

(8) References. Complete citations for the reference material used in conducting the study should be presented in a separate section of the study report. The citations should include author(s), title of the reference document, agency/publisher that prepared/published the document, location (city and state) of agency/publisher, and date of publication.

(9) Appendices. Appendices should be included to provide detailed documentation of specific aspects of the study; for example, expanded listings of data summarized in the body of the report, detailed listings of computer output and/or statistical analyses, Commission public hearing transcripts, minute orders, resolutions, etc.

The project report should be written, reviewed, and distributed in accordance with standard Department practice. To assure consistency of style and format, the report should be written by one person, though other individuals are likely to be involved in conducting certain aspects of the study analyses. Copies of the preliminary draft report should be distributed to the appropriate District and Division personnel for review. Following this review, and after making any necessary revisions and modifications, the final draft of the project report should be submitted to SDHPT Administration for review and approval.

Following the Administration's approval of the project report, a publication draft should be submitted to the Commission for review and approval. The final project report should then be typed, proofread, printed and bound, and distributed in accordance with Department policy. Project reports which are to be released to the public should be sealed and signed by a Registered Professional Engineer.

V. BYPASS ROUTES

PURPOSE OF BYPASS ROUTES

Bypass routes are typically intended to accommodate traffic that passes through towns or cities, but have no destination within the community. Bypass routes, when properly planned and operated, can reduce the amount of traffic on city streets and reduce the delays experienced by through traffic. However, a bypass typically attracts a number of highway-oriented land developments. These developments are primarily commercial in nature, and, in some cases, can negate much of the delay savings that through traffic would otherwise realize. Moreover, the construction of bypass routes can significantly alter the functioning of the bypassed community's economy.

The planning, construction, and efficient operation of bypass routes must address a number of technical, economic, and political issues. The technical issues center around determining the amount of traffic and delay savings necessary to justify the construction of bypass routes and the type of access control strategies which should be implemented to insure that the trip desires of external traffic are served in an efficient manner.

The primary economic issues concern the cost effectiveness of the bypass route and the effect(s) the bypass might have on the local community's economy. of the local. While the Department currently employs objective criteria in assessing the former, the latter is largely a political matter which is addressed on a case-by-case basis.

In addition to the political issues which arise in connection with the process of determining the need and/or feasibility of bypass routes, questions concerning the amount and type of access control to be enforced on bypass routes is largely a political/policy matter. The Department does not currently have in place any general policies that provide guidelines concerning access control for its various types of highway projects.

The following sections of this chapter outline a basic framework for developing guidelines for planning bypass routes. The intent of this chapter is to identify the key issues which need to be addressed and to outline various alternative policy and technical scenarios which the Department may wish to consider. Like several other sections of this Guide, it is envisioned that the contents of this chapter will evolve over the course of this research study into standard, specific guidelines for addressing the major issues concerning bypass

route planning and operation.

PLANNING GUIDELINES FOR DETERMINING THE NEED FOR BYPASS ROUTES

The need for bypass routes should be assessed on the basis of the following three factors:

(1) Level of Service. It is recommended that the Department develop minimum (threshold) values of travel time savings which must be achieved to justify bypass routes. The Department's Trunk System Task Force is currently considering such guidelines. The results of the Task Force's recommendations will be incorporated into subsequent versions of this Guide. In assessing the level of service impacts of proposed bypass routes, the impacts of removing (diverting) through traffic from local streets and the level of service impacts of alternative access control strategies should also be considered.

(2) Cost Effectiveness. The Department currently evaluates the effectiveness of new loop and bypass projects on the basis of cost per vehicle-mile (C/VM_L), with an adjustment for truck traffic (2.4 passenger cars/truck). The cost effectiveness index for new loop and bypass routes is calculated as follows:

C/VM_L = (Construction + Right-of-Way Costs)/[(Existing ADT + Truck Equiv.)(Length)]

The Department currently uses a threshold value of $600/vehicle-mile to identify cost effective bypass route projects.

(3) Community Impacts. In addition to level of service and cost effectiveness considerations, bypass route studies should also address the impacts that such routes can have on bypassed communities. The impacts of bypasses on the local economy is largely a function of the level of access control exercised along the bypass route. Complete control (restriction) of access is needed to insure that the level of service objectives of bypass routes are achieved. However, unless some degree of access is provided, economic development and the local economy, in general, could suffer. The primary community impact concerns which need to be addressed center on the extent to which local communities should be involved in the planning process and the

tradeoffs (in terms of level of service and cost effectiveness) associated with various departmental policies concerning access control for bypass routes. The Department needs to develop specific policies and procedures for (1) assessing the local impacts of various alternatives concerning the location and operation (i.e., access control) of bypass routes and (2) determining the degree to which local communities should be involved in decisions concerning the planning and operating strategies of bypass routes.

The remaining sections of this chapter discuss, in general terms, the implications of various access control strategies and the local economic impacts of bypass routes.

ECONOMIC IMPACTS OF BYPASS ROUTES

The majority of past studies have focused almost exclusively upon the economic effects on small to medium-sized communities caused by rerouting a highway around the town to avoid central area conflicts and congestion. These studies have typically been conducted for public information and public relations purposes. The studies reduce the friction and controversy arising mainly from business interests in the bypassed town who fear that removal of through traffic from the main street will undercut their sales and impair the local economy. As a result, most bypass studies have been designed to address the following questions: Are retail sales harmed by bypassing? Does the economy of the bypassed community suffer? What, if any, specific types of businesses are disadvantaged by bypass routes?

Though it is difficult to identify and isolate the economic effects attributable solely to bypasses, the evidence from past studies strongly suggests that bypass routes do not have a measurable, negative impact on the economy of the bypassed community. In fact, an early study (7) of bypass routes in 72 communities suggests that any losses in sales due to the rerouting of through traffic may well be offset by an extension of the local trade area. That is, more remote areas can be drawn into the local trade area as a result of improved highways which provide less congested business districts for shopping.

A recent study (8) of 40 bypass route projects in Texas found that bypass highway improvements have a statistically significant and positive influence on county employment levels. Bypass routes were also found to have a positive, though "not quite statistically

significant," influence on city manufacturing employment and county real wages (8).

ACCESS CONTROL CONSIDERATIONS

If the primary objective of bypass routes is to reduce the delays experienced by through traffic, then access to these routes needs to be limited. However, controlled-access roadways require considerably more right-of-way than other types of roadways and, as a result, are much more costly than comparable facilities with less restrictive access controls. This additional right-of-way is needed to control and/or prevent land development adjacent to the bypass route and/or to accommodate frontage and service roads. Moreover, controlled-access bypass routes are likely to generate more local resistance and controversy than other less restrictive facilities.

Unrestricted access typically attracts highway-oriented commercial land developments that can negate much of the delay savings which bypass routes are intended to provide, unless a supporting system of access and circulator roadways (e. g., frontage roads) is provided. When access to bypass routes is not restricted or accommodated in an efficient manner, the commercial activities of the bypassed community may simply move to the bypass route. In such situations, bypass routes can have a substantial economic development impact yet fail to effectively serve the movement of through traffic.

From a purely technical standpoint, then, bypass routes should be planned and operated so as to facilitate the movement of through traffic. To achieve this objective, access to bypass routes should be completely restricted. From a political and economic standpoint, however, this may not be feasible. Therefore, the Department should evaluate its current procedures and policies (or develop new ones) regarding access control for bypass routes. The Department's Trunk System Task Force is currently considering these basic issues, but additional work likely will be needed to formulate comprehensive procedures and policies regarding access control for the state's highway system. At this point, it is recommended that the Department evaluate the economic and political feasibility of limiting access to bypass routes through the provision of frontage/service access roads.

APPENDIX A

INTERCITY ORIGIN-DESTINATION STUDIES*

* The material in this appendix was developed for the "Austin/San Antonio Origin-Destination Study" conducted for the Department in 1987. Though the material frequently refers specifically to the Austin/San Antonio corridor, the study design is applicable to intercity highway corridors, in general.

1. REVIEW OF ORIGIN DESTINATION SURVEY METHODS[1]

1.1 ROADSIDE INTERVIEW

In the roadside method, interview crews stop passenger cars and commercial vehicles at roadside locations and interview the drivers. The data are recorded on prepared forms, and the information obtained may include the following:

- Type of vehicle
- Number of occupants per vehicle
- Trip origin and destination
- Trip purpose
- Trip frequency
- Routes traveled

A trained interviewer can complete 30 to 40 interviews per hour, provided there is sufficient traffic for continuous interviewing. In addition to interviewing a sample of drivers, other observers count and classify all traffic passing the interview station. These counts are used to develop factors for expanding the interview data to represent all vehicles.

If the survey is concerned only with trip data on a single route, interviews at a single midpoint location might suffice. If data are required on all traffic entering and leaving a city, it is necessary to select interview stations on all major routes radiating from the city.

1.1.1 Requirements for Implementation

Past studies using roadside origin-destination (O-D) interviews employed different sampling fractions which ranged from 20 percent to 50 percent of the traffic, depending on the amount of traffic and the accuracy sought. As a practical matter, drivers of vehicles are often interviewed in some predetermined pattern. For example, if a 50 percent sample is required, the crew may interview drivers of three vehicles and skip the next three vehicles; for a 15 percent sample, the crew may interview drivers of three vehicles and skip drivers of the next nine vehicles. The number of interviewers depends on the traffic volume at the survey station and the required sampling rates. For example, in order to keep vehicle delays

[1] Note: The material in this section comes, in large part, from References 1-3.

to a minimum, as many as 12 interviewers may be required for a 25 percent sample at a location on a 4-lane highway with an hourly volume of 1,200 vehicles in one direction. The number of interviewers required increases rapidly with increased hourly volumes and/or sampling rates.

In addition to interviewers, a typical crew for conducting a roadside interview at a single location in both directions of a high-volume facility would include:

- A survey party chief
- Two to four traffic recorders
- Two to four uniformed law enforcement officers.

The recorders count, classify, and record traffic volumes, while the interviewers conduct the O-D survey (interview drivers). The law enforcement personnel would be responsible for traffic control activities in the vicinity of the interview station(s). Additional personnel would also be required to implement traffic control measures upstream of the interview stations.

1.1.2 Advantages/Disadvantages of Roadside Interview

Advantages:

(1) Due to the personal contact between respondent and interviewer, complete and accurate information on travel is generally obtained.

(2) Response rate is high (relative to voluntary return techniques), thus minimizing possible survey errors and biases.

(3) Good coverage of the population is insured because a sample is selected from all vehicles and interviewed.

(4) Samples (vehicles) can be chosen from the traffic stream to satisfy sample size requirements.

Disadvantages:

(1) This technique is expensive due to the large number of personnel required, particularly on high-volume facilities. If personnel are limited, survey operations must be confined to one or two survey stations per day, and the survey must be extended over a number of days.

(2) Traffic must be stopped for long periods in order to complete interviews with

drivers. On high-volume facilities, traffic delays during the survey may be critical. Once considerable delays occur, potential interviewees may become annoyed and less likely to cooperate, thereby lowering response rates. Traffic diversion may also occur and result in survey under-coverage.

(3) On very high-volume facilities which require a large number of interviewers to keep pace with arriving vehicles, the complexity of setting up sites, traffic control, and managing the survey increases.

(4) This technique can be hazardous on high-volume facilities. Since interviewers must operate on the highway and interrupt the regular flow of traffic, precautions must be taken to protect survey personnel and motorists.

1.2 POSTCARD SURVEYS

There are two general methods of obtaining O-D data by the use of prepaid return postcards. The first method involves distributing postcards to drivers at some location on their travel route. The second involves mailing the postcards to vehicle owners. The second method is generally referred to as a "controlled postcard survey." Both methods are suitable when traffic is heavy and cannot be stopped long enough for an interview.

In the first method, postcards are distributed at roadside stations. If possible, these stations should be located at points where traffic flow is impeded for one reason or another, such as at toll booths. The information requested is similar to that obtained at the roadside interview stations. The postcards are precoded to indicate the time of day and the station from which they were distributed. Vehicle classification may be obtained by a question on the postcard or by different colored cards. At each station, classification and 24-hour volume counts are made to permit expansion of the returns to represent all vehicles.

In the controlled postcard procedure, a list is prepared of all owners of passenger cars, taxis, and trucks registered within the study area. Prior to mailing, the cards are precoded for zone location and vehicle classification. The original list contains the total number of vehicles of each type. This permits expansion of the returns obtained to represent the total vehicle population. The controlled postcard procedure can also be modified to make use of a list of licensed drivers within the study are instead of a list of vehicle owners. Each person on the list is sent a postcard which provides space for

recording the origin and destination of all vehicle trips made on a specified weekday.

1.2.1 Requirements for Implementation

Return rates for postcard surveys are not high, typically in the range of 25 to 35 percent. In the controlled postcard procedure, follow-up of non-response can be easily undertaken to increase the response rates. However, follow-up is not possible for the roadside distribution postcard procedure. Therefore, in order to encourage a high rate of postcard return, the questions on the postcard should be limited in number and should be clear and simple to answer. If the return rate is unusually low, independent accuracy checking such as "screenline" traffic counts or socio-economic checks may be necessary. It has been reported that a return rate of at least 20 percent might be essential to the accuracy of this type of survey.

A number of major roadside distribution postcard O-D surveys conducted by the Texas Transportation Institute on urban freeways in Houston and San Antonio between 1981 and 1984 indicated a range of response rates from 25 to 37 percent, with an average response rate of about 32 percent. Table A-1 shows the number of postcards distributed and returned for these O-D surveys.

Table A-1. Response Rates for Recent TTI Postcard O-D Surveys

Survey Location	No. Postcards Distributed	No. Postcards Returned	Percent Returned
US-59S, Houston (1981)	75,000	27,410	37%
I-10W, Houston (1981)	75,000	27,220	36%
I-410, San Antonio (1984)	82,500	20,530	25%[a]
Total	232,500	75,160	32%

[a]The San Antonio Study included a mail-out survey using names and addresses obtained through a license plate sample (See Section 1.3). As a result, the observed response rate is probably lower than would be expected had the roadside-distribution postcard survey been used exclusively.

The questions on the postcard should be simple and in the range of 5 to 7 questions. In the case of the roadside-distribution method, the postcards should be coded in advance to indicate the station from which they were distributed, the time handed-out, the number

of cards handed-out, and vehicle type.

A typical crew at each station for the roadside distribution method on a high-volume facility would include:

- A survey party chief
- Two to four traffic recorders
- Two to four persons to hand-out postcards
- One to two uniformed police officers

As in roadside interviews, additional personnel would also be required to implement traffic control measures near the survey stations.

1.2.2 Advantages/Disadvantages of Postcard Surveys

Advantages:

(1) Good coverage of the population is insured because the vehicles sampled are selected from all vehicles.

(2) Field work can be completed in one day.

(3) Traffic delay is not likely to be a problem as in roadside interviews.

(4) Technique is relatively inexpensive and involves far fewer field personnel than roadside interviews.

Disadvantages:

(1) Personal contact is not made with respondent; thus complete and accurate information is not guaranteed.

(2) Response rates are lower than roadside interviews, and sample may be biased due to better cooperation by certain groups of drivers.

(3) Through trucks and passenger vehicles may not provide as high percentage returns as those in roadside interviews.

(4) Slowing down or stopping traffic is required.

(5) There is no provision for follow-up of non-responses (for roadside distribution method).

1.3 LICENSE PLATE SURVEYS

Two types of license plate surveys may be used to obtain O-D information. The first

method involves recording license plate numbers as vehicles pass each survey station. By comparing (matching) license plate numbers recorded at successive survey stations, vehicle travel patterns through the study area can be traced.

A large amount of work is necessary to match license plates and to trace the route origin and destination of each vehicle. While computer programs are available for data processing, usually not more than 60 percent of the license numbers can be matched (and traced) using this technique.

An alternate and more detailed license plate technique involves recording license numbers, identifying ownership from vehicle registration records, and sending a mail-back questionnaire to each vehicle owner. In this regard, this method is similar to the postcard techniques described earlier with one notable exception: In the license plate technique, questionnaires may never reach drivers of out-of-state or leased vehicles whose license plates were previously selected. This will invariably result in non-coverage of certain subgroups of the population. This non-coverage problem is not likely to exist in the roadside-distribution postcard technique.

Both methods are adaptable to locations where traffic is too heavy to be stopped for driver interviews.

1.3.1 Requirements for Implementation

The license plate trace method requires large numbers of observers, since all stations must be operated simultaneously. While the exact number of observers is a function of the number of origin and destination points along the route being studies, at least two observers per station should suffice. Similarly, the license plate registration mail-back questionnaire method could be implemented by two observers per station. However, the stations need not operate simultaneously, and the sample could be collected over several days.

1.3.2 Advantages/Disadvantages of the License Plate Survey

License Plate Trace Method Advantages

(1) Field organization is simple.

(2) There is no interference with moving traffic.

(3) Likelihood of obtaining unbiased sample is good.

Disadvantages:

(1) Matching field data is extremely difficult.

(2) Large numbers of observers are required since all stations must be operated simultaneously.

(3) A large element of personal error in recording license numbers exists.

License Plate Mail-Back Questionnaire Method Advantages

(1) This technique has the same basic advantages as the voluntary return postcard technique. However, non-coverage of some subgroups such as leased or out-of-state vehicles may occur.

(2) This technique is safer, because traffic is not stopped.

(3) If a camera can be used to record license plate numbers with sufficient clarity to enable the license plates to be read, a smaller number of field personnel will be needed.

(4) Follow-up of non-responses is possible.

Disadvantages:

(1) Personal contact is not made with respondents; thus complete and accurate information is not guaranteed.

(2) Fewer questions can be asked because of the voluntary response.

(3) Night operation is difficult.

(4) There may be non-coverage biases that must be carefully accounted for.

(5) The method is difficult to use economically and efficiently unless all motor vehicle registrations are on computer tape; because quick access is needed to obtain vehicle addresses for mailing questionnaires. (The questionnaire should be mailed out within 24 hours to be most effective.) This requirement is further complicated by out-of-state vehicles. If there is a substantial number of such vehicles it may be extremely difficult to mail out the questionnaires.

1.4 TAG-ON-VEHICLE/LIGHTS-ON SURVEYS

In the "tag-on-vehicle" method, a coded card is handed to the driver or fastened to

the vehicle as it enters the route or area of study. The driver is informed of the nature of the survey and told that the card will be picked up when leaving the route or survey area.

When the vehicle leaves the route or area, the time, station, direction of travel, and any other readily observed information are recorded on the pre-coded card. If traffic is heavy, the cards may be simply bundled into groups according to time intervals, and the time written on the top card of each bundle. This method produces results which have the same advantages and disadvantages as the license plate trace method described above.

A variation on this procedure is called the "lights-on" method. In this method, signs are used to request motorists entering the survey area to turn on their headlights for a specified time or until they leave the survey area. Counts are made of cars with headlights on at each exit point. A count should be made at the entrance point to determine the number of drivers who comply with the lights-on request. This information permits an adjustment of the results to account for non-complying drivers.

1.5 SYNTHETIC O-D ESTIMATION METHODS

A large number of methods/models to estimate O-D travel have been developed by researchers and transportation planners. They can be summarized under two general approaches.

1.5.1 Trip Distribution Models

Trip distribution models are generally estimated or calibrated using information on O-D travel from some base-year surveys, population, various activities, socio-economic characteristics, and some measures of travel impedance. The model estimation requires assumptions concerning the relationship between O-D travel and factors such as population, various activities, socio-economic characteristics, and travel distance or travel time. Model parameters are then estimated and, in turn, used to forecast the O-D travel for different time frames and/or different locations. The forecasted O-D results are usually differ with trip distribution models, depending on the model structures and the assumptions employed. Furthermore, the accuracy or reliability of the modeling results is difficult to test and typically involves a comparing of the modeling results with actual O-D observations.

1.5.2 O-D Estimation Using Available ADT Data

Estimating O-D by using available ADT data decreases the usually high costs of obtaining base-year O-D data from actual O-D surveys. ADT data, in most cases, are available for all major roadways. In addition to the ADT data, this method requires critical assumptions concerning trip makers' travel behavior in route selection as well as estimates of trip ends at all origin and destination points. Iterative procedures are used to seek "equilibrium" within the network or to satisfy "optimal" conditions in order to yield the O-D travel associated with these conditions. The algorithms that have been used vary in the degree of complexity. Depending upon the problem formulation, the O-D travel results obtained are not necessarily unique but may have various sets of possible outcomes. As with the trip distribution models, the O-D results obtained from different estimation (or modeling) techniques will be different depending on the travel-behavior assumptions, the formulation of the problem, and the computational tools used for iterations. The accuracy of the results from this estimation method are also difficult to test unless they can be compared with observed O-D values.

1.6 SUMMARY OF SURVEY METHODS

In the context of the proposed corridor study (i.e., Austin/San Antonio O-D study), synthetic O-D estimation approaches are not suitable. The results generated by these methods will be questionable in the absence of an instrument to test for their accuracy. The present knowledge of trip-making behavior and processes is not sufficiently advanced to enable the conceptualization of a synthetic O-D model that does not require at least accuracy checking against actual O-D data before being applied to forecasting.

The results of sample surveys are always subject to some uncertainty because only part of the population has been measured and because of measurement errors. This uncertainty can be reduced by taking larger samples and by using superior instruments of measurement. But this usually costs time and money. The purpose of any experimental design, then, should be to provide a sufficient amount of information at minimum cost. For the current study, three key considerations--cost, accuracy, and adaptability of the survey method to the problem at hand--must be taken into account in selecting an appropriate O-D survey method.

Table A-2 presents a general summary of the traditional O-D survey methods discussed in the preceding sections. The methods shown in Table A-2 have been arranged in descending order in terms of cost and accuracy.

Both the license plate trace method and the tag-on-vehicle/lights-on surveys are not applicable to a large intercity traffic corridor such as the Austin/San Antonio corridor due to the extreme difficulties in planning and implementing the survey. The manpower requirement to implement either one of these methods on a corridor of this size would be unrealistic, and the analysis of the field data would be extremely cumbersome.

The license plate mail-out survey, which can be implemented without interrupting the flow of traffic, has a number of shortcomings. The most notable problem is that after the vehicles passing a station are selected and their license plate numbers read, it is difficult to send questionnaires to drivers of trucks or out-of-state vehicles, and it is almost impossible to reach drivers of leased vehicles. This survey method will, therefore, result in non-coverage of many sub groups within the population which will result in biases and errors in the survey that cannot be easily corrected. This is a particularly serious problem if a substantial proportion of traffic on this corridor is made up of trucks, and leased and out-of-state vehicles. Furthermore, in reading license plate numbers in the field, reading and recording errors are likely to exist, reducing the size of the usable sample of vehicles.

The controlled postcard survey method, which utilizes vehicle ownership or licensed driver information, suffers the same shortcomings as the license plate mail-out method in its inability to effectively survey trucks, and leased and out-of-state vehicles. This method is therefore, considered unsuitable for this study.

Given the importance of the proposed corridor study, the roadside interview and the postcard distribution methods are both justified in terms of costs and accuracy. Indeed, both are similar in providing good coverage of the vehicle population and in the amount of information that can be effectively sought from the drivers. In terms of costs and manpower requirements, the roadside interview method, on the average, requires three to four times more field personnel than the postcard distribution method; and this estimate can be much higher for high-volume facilities. A trained interviewer can complete about 30 to 40 interviews in an hour while postcards can be handed out to drivers every 4 to 5 seconds. The response rate of the roadside interview method, however, may be up to three times as

Table A-2. Summary of O-D Survey Methods

	Survey Method	Advantages	Disadvantages	Manpower Requirements per Survey Station	Recommended Sample Size[b]	Typical Response Rates
1.	Roadside Interview	• Complete information • High response rate • Better sampling control	• Relatively expensive • Traffic delays • Hazardous	• 10-20 persons/ station[a] • 2-4 police officers	20%-50%	100%
2.	Postcard Surveys	• Can be completed quickly • Less traffic delay • Relatively inexpensive • Good population coverage	• Possible bias due to better response by some drivers • Low response by thru and out-of-state traffic • Requires stopping traffic • No provision for followup of non-response	• 5-9 persons/station • 1-2 police officers	60%-80%	25%-35%
3.	License Plate Surveys					
	a) "Trace" Method	• Simplicity of field organization • No interference with traffic • Unbiased Sample	• Data analysis is difficult • Large number of stations required • Possible recording errors • Survey stations must operate simultaneously	• 2-3 persons/station	35%-50%	60%[c]
	b) "Mail-out"	• Similar to Method No. 2, except followup of non-response is possible • Stations need not operate simultaneously	• Same as Method No. 2, except does not require stopping traffic • Requires access to vehicle registration files	• 2-3 persons/station	60%-80%[d]	20%-35%[d]
4.	Tag-on-vehicle/ Lights-on Survey	• Same as Method No. 3a, except may result in minor traffic delay	• Same as Method No. 3a, except less recording errors	• 2-3 persons/station	100%	-

[a]Number of interviewers varies with traffic volume but on the average is about 3-4 times the number of persons required to hand out postcards. The above estimate is for relatively low hourly traffic volumes.
[b]Sample sizes have been adjusted for typical response rates to insure at least 20% sample.
[c]Response rate is estimate of percentage of license plates which can be traced.
[d]Response rate can be increased by follow-up of non-responses.

high as that of the roadside distribution postcard method. Despite its higher response rate, the interview crew will need to work at least as long as the postcard distribution crew in order to obtain a sufficient number of responses. The lower response rate of the roadside distribution postcard method can be compensated for by designing for however, a larger sample size.

In terms of adaptability, the postcard-distribution method is more desirable in terms of traffic delays, station set-up, traffic control plans, survey management, and safety to the survey crew and motorists. On a high-volume facility such as Interstate 35, it is not practical to stop traffic to complete interviews with drivers on-site because traffic congestion and delays will be excessive even with a large interview crew. Furthermore, as the number of interviewers increases, so does the complexity of setting up the site and managing the survey in order to maintain safety and to minimize traffic delays and confusion. Previous TTI experiences with the roadside distribution postcard method have shown that with a good traffic control plan, well-trained survey personnel, and the use of an appropriate vehicle selection technique, this survey method can be safely implemented without causing any substantial delays to traffic.

Another method for estimating O-D data is a combination roadside distribution postcard survey and roadside interview survey. Past TTI experience suggests that such a combination would not enhance the amount of information obtainable, nor would it improve the quality of the survey results. The suggested combination approach would involve distributing postcards to drivers during high-volume time periods and conducting on-site interviews during low-volume time periods. However, even during low-volume periods on Interstate 35, the time required to conduct on-site interviews could cause considerable traffic delays unless the interviews could be conducted off the roadway. If the on-site interviews were to be conducted on the roadway, it appears unlikely that a substantial percentage of the traffic could be sampled without causing excessive delays.

Based on these considerations, the roadside distribution postcard survey method appears most suitable for the study corridor. A detailed plan for implementing this method in the study corridor is given in Section 3. The detailed study plan is preceded by a discussion of sample size considerations in Section 2.

2. OVERVIEW OF SAMPLE DESIGN CONSIDERATIONS

2.1 INTRODUCTION

Sample design of an intercity origin-destination study consists of many tasks, including the following:

(1) Defining the corridor of interest and the origin/destination points within the corridor,

(2) Identification of survey stations in the corridor,

(3) Selection of an appropriate survey method,

(4) Design of sample size to insure statistical validity and reliability of the results,

(5) Selection of vehicles to be interviewed, and

(6) Independent checking of the accuracy of the survey results.

In origin-destination studies, there are two main sources of errors: sampling errors and non-sampling errors. In order to insure the accuracy of the results, sampling errors must be minimized. To insure that the survey results are representative of the corridor traffic, non-sampling errors also must be minimized.

Sampling errors or sampling variance are measures of statistical accuracy of the O-D estimates obtained from the survey. Sampling variance arises because it is highly unlikely that drivers of all vehicles in the corridor will be interviewed. Sampling variance can be controlled at the sample-design stage by planning for a sufficient number of vehicles to be included in the sample. As a rule, sampling variance decreases as the sample size is increased. Sampling variance is also random in nature (i.e., it falls on either side of the estimates). As a sample size increases, sampling variance becomes less of an issue, and the problem of sample size is almost negligible for a sample of 10,000 cases or more. The number of vehicles (or the sample size) required at any one station is a function of the desired accuracy of the O-D estimates and the variability within the population studied. For an intercity origin-destination survey, such variability depends on the numbers of origin-destination pairs within the corridor for which travel estimates are needed and on the distribution of all travel among these pairs. The procedure for determining sample size requirements is described below.

Non-sampling errors are not likely to be random in occurrence, and they do not

usually decrease in magnitude with larger samples. Non-sampling errors are made up of at least two components:

(1) Biases due to non-coverage and non-response, and

(2) Errors associated with data collection and data processing procedures.

Biases due to non-coverage and non-response can be minimized by selecting a survey method that will insure (1) a sufficient response rate and (2) as complete a coverage of all different subgroups of the population as possible. Errors associated with data collection and data processing procedures can be minimized with tight quality control and good management of the survey team.

2.2 SAMPLE SIZE REQUIREMENTS

Sample size determination for roadside interview, postcard distribution, and license plate reading follows the same procedure. A minimum sample size required at a given survey station is the number of vehicles sampled at that station whose drivers successfully complete the postcards or the interview. A minimum sample size required for an origin-destination survey of vehicles passing through a survey station is usually expressed as a sampling rate (i.e., a ratio of the number of vehicles sampled to the total number of vehicles passing through). The sampling rate is a function of the following:

(a) p: proportion of traffic volume at the survey station with a particular O-D
p = volume of a particular O-D interchange/traffic volume at the survey station

(b) w: desired accuracy (% error) of p

(c) N: traffic volume at the survey station

(d) Z: normal variate which is associated with a specified level of confidence in estimating the O-D interchange volume

The sample size formula is given by (4):

$$r = (Z^2pq)/((N-1)w^2 + Z^2pq)$$

where:

r = required sampling rate

q = (1 - p)

To apply the sample size formula, some estimate of the traffic volume, "N," at the

survey station must be known. A desired accuracy of the proportion p must be specified as must a level of confidence in estimating "p." One other quantity that must be specified is p, the proportion of traffic volume at the survey station with a particular O-D. This proportion is usually not known during sample size determination. What must be specified, instead, is a minimum O-D trip interchange volume to be obtained from the survey with the desired accuracy level. In the context of this study, this minimum O-D trip interchange volume may be in the range of 2 to 10 percent of the traffic volume at the survey station.

Tables A-3 through A-5 present approximate sampling rates ("r") for a range of ADT's ("N") and accuracy levels (error rates) from ± 5 percent to ± 15 percent. All calculations assume a 95 percent confidence interval. Lower confidence intervals will result in lower sampling rates for a given ADT and accuracy level.

The sampling rates shown in Tables A-3 through A-5 assume a 100 percent response and must be adjusted for non-responses as follows:

Number of vehicles sampled = (Sampling rate x Traffic volume)/Response rate

Table A-3. Approximate Sampling Rates for Error within ±5 percent at 95 percent Confidence Interval

50,000	.10	.06	.03
60,000	.09	.05	.02

Notes:

N = Traffic volume at survey station

p = Minimum O-D trip interchange volume to be estimated from the survey with the desired accuracy level (expressed as proportion of N).

Sampling rates assume 100 percent response and must be adjusted for non-responses as follows: Number of Veh. Sampled = (Sampling Rate x Traffic Vol.)/Response Rate.

The implication of the equation given above is that for those survey methods with less than 100 percent response, the precision obtainable often becomes a matter of what percentage of the traffic can be realistically surveyed. For example, for the postcard survey methods, which typically have response rates on the order of 30 percent, only those schemes with

sampling rates in the range of 15 to 25 percent should be considered. Assuming a 30 percent response rate, 50 to 80 percent of the vehicles would need to be surveyed under these schemes.

3. STUDY DESIGN

3.1 SAMPLING PLAN

3.1.1 Survey Method

The general review of O-D survey methods presented in the preceding sections suggests that the roadside interview and the roadside distribution postcard methods may be justified in terms of costs and accuracy. In terms of adaptability, however, the roadside interview method may not be suitable for the study corridor. On a heavily traveled interstate freeway, such as I-35, it may not be practical to stop traffic for driver interviews. As a result, it is the recommendation of this study that a roadside distribution postcard survey be implemented in the study corridor. Implementation of this method should provide an accurate estimate of O-D flows in the corridor at a reasonable cost without causing excessive delays to the motoring public.

A sample postcard survey form is shown in Appendix A-1. The survey form has been designed to solicit information concerning vehicle type, trip purpose, trip origin and destination, vehicle occupancy, and trip frequency. The suggested survey form requests street address, city, and zip code of the trip origin and destination. This information will make it possible to code O-D zones with sufficient detail to evaluate the range of improvements being considered for the corridor. The questionnaire portion of the form should be printed on the back of a prepaid, preaddressed postcard. Also, each questionnaire should be individually numbered to facilitate recording the time and location of distribution.

3.1.2 Survey Stations

Based on discussions with SDHPT personnel and a review of the objectives of the corridor study, survey stations should be considered at the following locations (Figure 1):

(1) I-35, between San Marcos and San Antonio, south of SH 46 (bi-directional)

(2) I-35, between Austin and San Marcos (bi-directional)

(3) SH 123, between I-35 and I-10 (bi-directional)

(4) US 183, Between SH 21 and I-10 (bi-directional)

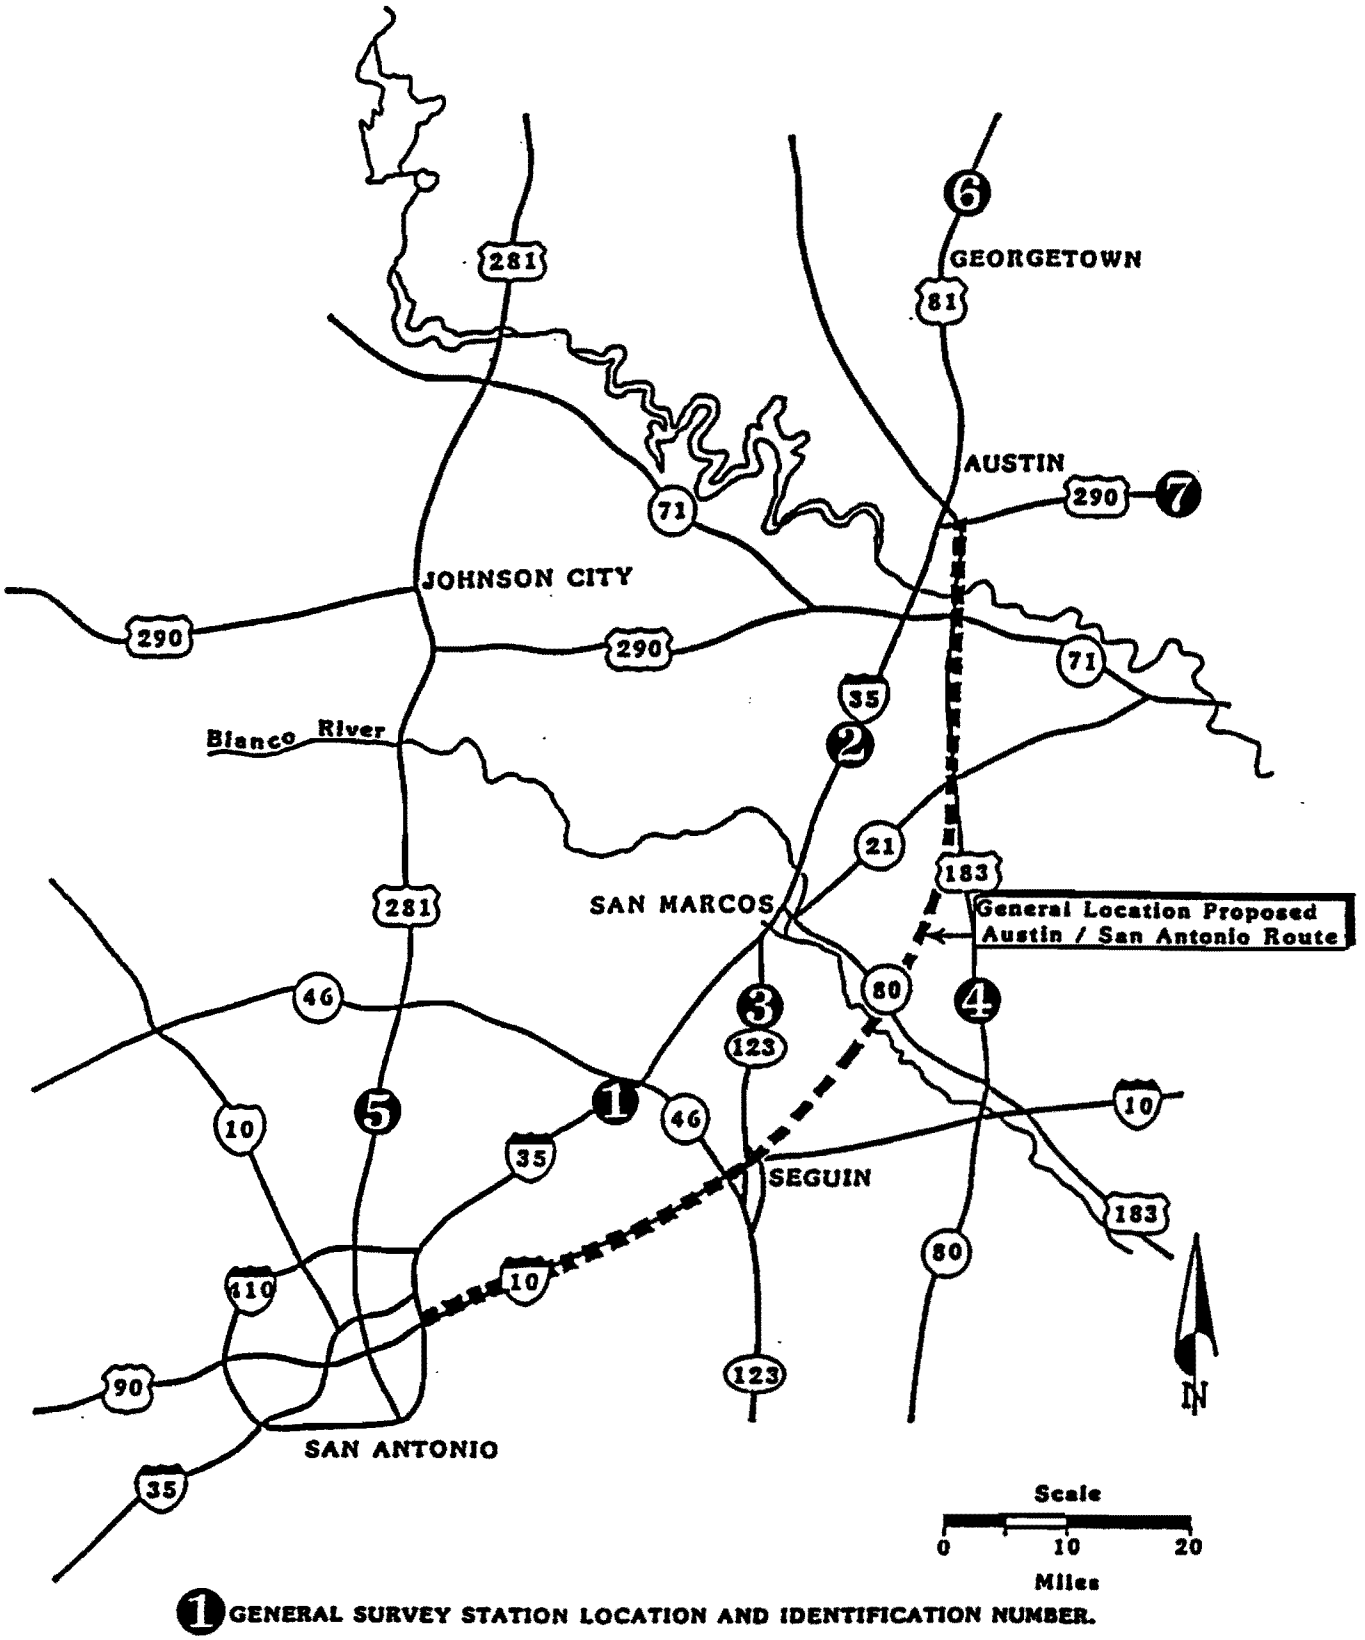

Figure 1. General Locations of Recommended Survey Stations, Austin/San Antonio Study Corridor.

(5) US 281, north of San Antonio between FM 1604 and SH 46 (bi-directional)

(6) I-35, north of Georgetown (bi-directional)

(7) US 290, east of Austin, east of SH 95 (bi-directional)

These survey station locations should provide a representative sample of travel patterns in the study corridor. The justification for the bi-directional nature of the recommended stations is presented in Section 3.1.3.

Depending upon the specific improvements to be evaluated in the corridor study, it may not be necessary to establish survey stations at all the locations listed above. The I-35 stations between Austin and San Antonio and the stations on SH 123 and US 183 will provide samples of intercity and through traffic as well as traffic with origin-destinations at key intermediate points. These stations are particularly important in assessing the potential feasibility of an alternate Austin/San Antonio route to the east of I-35.

The US 281 station would sample potential traffic for an alternate route between Austin and San Antonio to the west of I-35, and the US 290 and I-35 (north of Georgetown) stations would provide samples of traffic that might use an I-35 bypass to the east of Austin.

In terms of the priority of these recommended station locations, only some general guidelines concerning the "minimum" and "desirable" number of stations is appropriate at this time. Specifically, should it become necessary to reduce the number of recommended stations, the following guidelines are suggested:

(1) If the intent of the corridor study is to assess the feasibility of alternate routes to the east and west of I-35 and an I-35 bypass to the east of Austin, survey stations at the seven locations indicated on Figure 1 should be established.

(2) If the scope of the corridor study is restricted to an assessment of the feasibility of an alternate route to the east of I-35, stations 5, 6, and 7 could be eliminated from consideration.

The following criteria should be used to identify precise survey station locations.

(1) Sight-Distance. The primary consideration in selecting survey stations should be safety. Survey stations should be located on flat, straight roadway sections which are clear of structures or other obstructions that could reduce sight-distances. Level and straight sections of highways with an unrestricted sight

distance of 800 feet or more in each direction from the station should be used (2). Stations should not be at or near intersections. Care should also be taken to avoid possibilities of traffic bypassing the station.

(2) Roadway Cross-Section. Wherever possible, survey stations should be located where roadway width is at its maximum. On I-35, survey stations should be located on sections with inside and outside shoulders. By using the freeway shoulders it is possible to set-up four channel service areas for postcard distribution. On non-interstate roadways, survey stations should be established on four-lane sections, if possible.

(3) Traffic Catchment Area. Survey stations should be located to intercept a representative sample of intercity traffic. As a general guide, survey stations should be located near the midpoints of the roadway links to be surveyed.

The roadway inventory data presented in Appendix A-2 should be useful in identifying candidate station locations. Final station selection, however, should be based on field inspections of the candidate locations.

In addition, to the general survey station locations discussed above, SDHPT staff have indicated a need to conduct a special survey of truck traffic on I-35 between Austin and San Antonio. Since it is reasonable to assume that nighttime truck O-D patterns on I-35 differ significantly from daytime patterns, it has been suggested that the feasibility of a nighttime truck O-D survey be examined. There are a number of jurisdictional and procedural issues that need to be resolved, and only some general guidelines for conducting such a study can be suggested at this time.

In terms of survey locations, the two truck check-stations on I-35 would appear to be the most likely candidate survey stations (North- and southbound check-stations are located near southbound milepoint 210). The use of these check-stations for survey purposes, however, would need to be coordinated with the Texas Department of Public Safety (DPS). The primary issue here is the extent of DPS involvement which would be needed to conduct surveys at the check-stations. Department of Public Safety manpower requirements and availability, as well as DPS policy regarding night-time operation of check stations, will need to be assessed in making an initial determination of the feasibility of the truck survey.

Assuming the necessary DPS cooperation can be secured, the issue of trucker

cooperation also needs to be carefully considered. Past TTI truck survey efforts have shown that truck drivers are not particularly interested in participating in traffic surveys. Hence, on-site interviews may be necessary to obtain sufficient response. Given the relatively low night-time truck volumes on I-35 (see Table A-6), it should be possible to conduct on-site interviews with a survey crew of three to four interviewers per station without causing excessive delays.

While the possibility of conducting night-time truck surveys at the check-stations appears to merit consideration, there are a number of alternative approaches to the problem that should also be considered. For example, if it could be established that night-time truck traffic is predominantly through-traffic, a carefully planned volume counting program could be used to estimate general travel patterns.

A possible secondary data source that should be investigated is the DPS Motor Carrier Registration file. All commercial motor carriers that operate in the state are required to purchase a permit, and the information filed to obtain this permit may contain travel-related data. Additionally, this registration file could possibly serve as a sampling frame for a mail-out and/or telephone survey of trucking firms.

Table A-6. Night-Time Truck Volumes on I-35 near the Blanco River

3.1.3 Survey Schedule

Survey scheduling issues which need to be considered include the following:

(1) Month and Day-of-Week Considerations. The choice of the month and day-

of-week of the survey will depend upon whether "typical" or "peak" O-D data are desired. Tables A-7 through A-12 summarize monthly, daily, and seasonal traffic volumes as a percent of AADT from several permanent traffic recorders in the corridor. As might be expected, the summer months of June through August typically account for the highest percentages of the AADT. The fall months of September through November, on the other hand, appear to be more representative of the AADT.

In terms of average daily variations in the AADT, Mondays through Thursdays appear to be "typical" days. Fridays, with their high percentages of pre-weekend traffic, tend to be higher than average traffic days.

Based on these considerations, it is recommended that the Austin/San Antonio O-D survey be conducted during the summer months (June through August) during the typical weekdays of Monday through Thursday.

(2) Time-of-Day Considerations. The O-D survey may be conducted over a 24-hour period, or more typically, during daylight hours. Given the hazards associated with night-time operations, it is recommended that, with the possible exception of the special truck study, survey operations be restricted to daylight hours.

It is also recommended that manual classification counts of traffic in the vicinity of the survey stations follow the same hours as those for the O-D survey operations. Automatic traffic counts near the survey station, however, should be carried out 24 hours per day. Since the O-D data obtained from the O-D survey must be expanded to represent the entire population and to reflect 24-hour volume, a minimum of three days of automatic traffic counts is recommended. (2).

3) Sample Intervals Within the Day. In most cases it will be impossible and undesirable to survey 100 percent of the vehicles passing through a survey station because this could cause undue delay and congestion. Thus, a representative sample of vehicles should be surveyed, the sample size depending upon the traffic volume occurring at a particular time. Practically speaking, there are two basic techniques for selecting a sample of vehicles. These methods, as outlined in Section 3.1.5, are called the platoon system and the alternate technique.

Under certain circumstances, it may be impossible to use a definite, predetermined pattern of selecting vehicles. This is especially true at very high volume stations where there could be considerable congestion and a potential safety hazard. The most important factor in such a case is to obtain an adequate sample without causing excessive delays. This issue is addressed in more detail in Section 3.1.5.

(4) One-Directional vs. Two-Directional Station Operations. In scheduling the survey and estimating manpower needs, the issue of whether each direction of travel is to be surveyed separately of simultaneously needs to be resolved. The Federal Highway Administration's guidelines (2) on conducting origin-destination surveys state ". . . two-directional surveying is necessary if hourly

data describing origins and destinations by direction are needed. It is generally assumed that although inbound traffic patterns are similar to outbound traffic patterns for a 24-hour period, the differences are significant enough on an hourly basis to warrant two-directional surveys. Some serious problems could arise in the analysis of the data if two-directional data are not available. Where sufficient personnel are available, it is desirable to survey traffic in both directions simultaneously."

Harmelink (5) suggests that one-directional surveys would produce larger errors than would two-directional surveys. Hajek (4) found that from actual O-D data that the errors for a 50 percent two-directional survey were very similar to the errors for a 100 percent one-directional survey. Hajek attributed this similarity in the errors to the daily variation in traffic which might have obscured the expected difference between the two-directional and the one-directional surveys.

In 1952, Miller, et al. (6) conducted an O-D survey in Richmond, Indiana, for the State Highway Commission of Indiana. The survey was operated for 16 hours a day at most stations. Both directions of traffic were surveyed at any one location. The station arrangement was exactly the same as if both directions were being surveyed at the same time, except that the stop sign for the direction not being surveyed was covered during the 15-minute periods when traffic could proceed without stopping.

Based on results of another survey at Lebanon, Indiana, Miller, et al. (6), reported that the universe tabulation of origin-destination trip frequencies indicated that the inbound and the outbound frequencies were not exact mirror images of one another but that some differences between the two directions existed. The percent differences were found to be higher for small trip interchange volumes than for larger trip interchange volumes.

Based on these past studies, it is recommended that if the study is aimed at estimating hourly O-D volumes as well as 24-hour O-D volumes, two-directional surveys should be used. Otherwise, one-directional surveys may be considered.

3.1.4 Sample Sizes

As discussed in Section 2, the method used in this study to estimate sample sizes is based on specifying a minimum O-D trip interchange volume (expressed as a portion of ADT) to be obtained from the survey with the desired accuracy level. Tables A-3 through A-5 summarize the resulting sampling rates for a range of ADT's and accuracy levels for error rates ranging from ±5 to ±15 percent. Because the response rate for the postcard distribution method is less than 100 percent, the required sampling rates after adjusting for the response rate will be much higher than those tabulated in Tables A-3 through A-5. Therefore, the level of accuracy obtainable in the field, from a practical standpoint, is sometimes governed by the maximum number of postcards that can be distributed during the study period without causing excessive delays to the traffic. This consideration is particularly important on high-volume facilities. For example, consider a survey station with a directional ADT of 20,000 vpd. In order to estimate a minimum O-D interchange volume of 600 vpd (3 percent of the ADT) within ±10 percent at 95 percent confidence, a sampling rate of 39 percent would be required (see Table A-4). However, when this sampling rate is adjusted to account for the fact that the typical response rate for postcard surveys is 30 percent, it becomes obvious that an accuracy of ±10 percent is not obtainable because the adjusted sampling rate is (0.39/0.30) x 100%, or 130 percent of the traffic. Thus, in selecting sample sizes for high volume facilities, it often becomes necessary to establish an upper limit on the percentage of the traffic to be surveyed. Past TTI experience suggests that an upper limit in the range of 50 to 60 percent is a reasonable value.

Table A-13 summarizes recommended sample sizes for each of the survey stations in the study corridor. The sample sizes are given in terms of the number of postcards to be distributed at each station. The sample sizes were estimated from rates given in Tables A-3 through A-5 and have been adjusted on the basis of an assumed postcard response rate of 30 percent. The recommended sample sizes are restricted by operational practicality that constrains the maximum number of postcard handouts to be within 60 percent of the traffic passing each station for facilities with ADT over 8,000 vph in one direction. General

[c]n = No. of postcards to be distributed.
[d]p = minimum O-D trip interchange volume which can be estimated from survey results with desired accuracy level (expressed as proportion of ADT).

remarks regarding the expected error limits of the O-D estimates obtained from the samples are also given in the table.

Based on TTI's past experiences with roadside-distribution postcard surveys, the distribution rates suggested in Table 13 appear reasonable. Additionally, the O-D estimates obtained from the samples should be sufficiently accurate for most planning applications.

Finally, it should be noted that the recommended sample sizes given in Table 13 are based on 1985 ADTs (the most recent data available at this time). Ideally, the recommended sample sizes should be checked by conducting volume counts at each of the survey stations in the weeks preceding the actual survey.

3.1.5 Selection of Vehicles

For roadside interviews or roadside distribution postcard methods, selecting sample of vehicles may be selected using the following techniques (2):

(1) Every nth vehicle in the traffic stream is selected. This technique may not be practical in the field.

(2) Clusters or platoons of vehicles arriving during a predetermined time interval are selected. For example, a platoon of vehicles arriving at the survey station during the first 15 minutes is selected while another platoon arriving the next 15 minutes is skipped. This is called a quarter-hour cluster selection. The time intervals can be of any duration but preferably a multiple of 5 minutes. The number of time intervals in any one hour period during which vehicles are selected or skipped depends on the sampling rate required. For example, a 50 percent sample may be obtained by selecting vehicles arriving during every other 15 minutes. A 75 percent sample may be obtained by selecting vehicles arriving during the first 45 minutes and skipping those during the next 15 minutes. It is desirable to maintain one predetermined selection pattern throughout the day unless traffic delays become excessive.

(3) The "alternate" method is used to vary the percent of vehicles sampled when delays and congestion become intolerable. For example, a 50 percent sample may be taken until congestion starts; then the sample can be reduced to 30 percent, and so on.

3.1.6 Expansion of Survey Results

Once the survey is completed and the O-D data from the survey are tabulated, the sample results must be expanded to the entire vehicle population for the corridor. Procedures to determine expansion factors are described below:

Let T be the number of vehicles in a universe of N vehicles which have a particular O-D. Suppose a sample of n vehicles is selected at random from the N vehicles, and t of these have the O-D, then (6):

$$\hat{T} = (N/n)\, t \quad \ldots\ldots\ (3.1)$$

where: $\hat{T}$ is an unbiased estimate of T

If the vehicles are selected by clusters or platoons, then an unbiased estimate of T is (6):

$$\hat{T} = (G/g)\, t \quad \ldots\ldots\ (3.2)$$

where:

G = number of clusters of vehicles in the universe

g = number of clusters of vehicles sampled

t = number of vehicles with the O-D which are found in the sample

t is calculated as follows:

$$t = \sum_{i=1}^{g} t_i$$

where:

t^i = number of vehicles in the ith cluster (i = 1, 2, 3, ..., G) which have the specified O-D

In equations (3.1) and (3.2), the quantities N/n and G/g are known as expansion factors. Estimations of the sampling variance for T are described in Appendix A-3.

If expansion factors by hour are required, and if the count and the classification data

at the site are available by hours of the day, the Federal Highway Administration (2) suggests the following formula for the hour factor (R_o):

$$R_o = (O \times V)/(P \times W) \text{ ..... } (3.3)$$

where:

O = actual number of vehicles in each group (cars, trucks, inbound, outbound) counted during the hour of interview

P = number of completed interviews obtained for each group of those vehicles during the hour of interview

V = average automatic count for "m" days of all vehicles during the applicable hour

W = actual number of all vehicles counted during the applicable hour on the day of interview

The hour factor should be computed separately for each of the following at each station for each hour of operation: inbound passenger cars, inbound trucks, outbound passenger cars, and outbound trucks. Taxis are included with passenger cars and buses are included with trucks.

The following 24-hour factor for each station is suggested by the Federal Highway Administration (2):

$$R_{24} = R_o \times S/L \text{ ..... } (3.4)$$

where:

R_o = hour factor

S = average automatic count for "m" days of all vehicles passing during the 24-hour period

L = average automatic count for "m" days of all vehicles passing during the group of hours that postcards are distributed

3.1.7 Independent Accuracy Checks

No sample survey is completely without errors or biases. The magnitude of errors or biases can be assessed and the survey results adjusted accordingly by means of independent accuracy checking. The types of accuracy checks that have been used in O-D surveys are socioeconomic checks and travel checks. Socioeconomic checks include data on income, occupation, auto-ownership, age, and sex. Travel checks include screenline traffic counts and data on trip length and vehicle miles of travel.

For survey methods such as the roadside distribution postcard technique, additional license plate readings of the vehicles receiving the postcards at the survey station can be an effective means of independent accuracy checking. From the license plate numbers, addresses of those receiving the postcards can be obtained through the vehicle registration file. Once the responses are mailed back, the proportion of non-responses by zip codes can be estimated. If the trip patterns are significantly influenced by zip code locations and if the eventual response rates were significantly different by zip code locations, appropriate adjustments can be made when expanding the actual survey results to the entire population within the corridor. In this way, potential biases or errors may be minimized or eliminated.

Travel checks such as screenline traffic counts usually involve 24-hour counting of the traffic crossing an imaginary boundary (screenline) at one or two locations within the corridor. The results from these screenline counts are then compared with those derived from the actual O-D survey. If necessary, the latter can be adjusted accordingly. Screenline travel checks are particularly desirable when the response rate is very low.

3.1.8 Pre-Survey Traffic Counts

Prior to implementing the O-D survey, preliminary traffic counts in the vicinity of each survey station should be made to validate the recommended sample sizes and to establish base data for assessing the representativeness of the survey samples. The following two pre-survey counts are recommended:

(1) 24-hour mechanical volume counts in 15-minute intervals. A 15-minute breakdown rather than hourly totals is recommended for high volume stations in order to anticipate periods of extreme peaking.

(2) Vehicle classification counts in 15-minute intervals. Classification counts will

need to be conducted manually and, as a result, should be restricted to daylight hours. A sample vehicle classification survey form can be found in Appendix A-1.

3.2 TRAFFIC CONTROL AND SURVEY STATION SET-UP

With the high traffic volumes likely to be encountered on many of the roadways to be surveyed, it is imperative that the surveys be conducted in a safe, efficient, and professional manner. Since very little time is spent with the actual distribution of postcards, inefficient station operations are usually a result of poor methods of vehicle entry and exit. Thus, the most significant contributor to safe and efficient operations at a high volume survey station is the entrance, terminal, and exit setup; that is, the physical lay-out of the survey station. There are many factors to consider when designing a physical setup arrangement including channelization, personnel positioning, and signing. These factors must be carefully considered in combination to determine the optimum setup for specific local conditions. With care, advance planning, and use of an appropriate survey method, travel data can be collected safely and efficiently, even on high volume roadways.

Figure 2 shows a recommended station setup for postcard distribution on an interstate highway. This same basic setup is also recommended for the non-interstate stations. The number of service channels, however, may need to be reduced to a maximum of two on non-interstate roadways.

All survey stations should have law enforcement officers on duty not only to insure safety, but when the officer is in view of the motorist, his representation of authority enhances cooperation.

Survey stations on high volume facilities generally will not operate continuously throughout the day. As a result, procedures for opening and closing the stations must be developed. Since covering/uncovering signs and installing/removing cones can be both time consuming and hazardous, these procedures need to be formulated well in advance of the field survey. It is recommended that station setup procedures be rehearsed in a laboratory environment to insure efficient field operations. Additionally, it may be desirable to

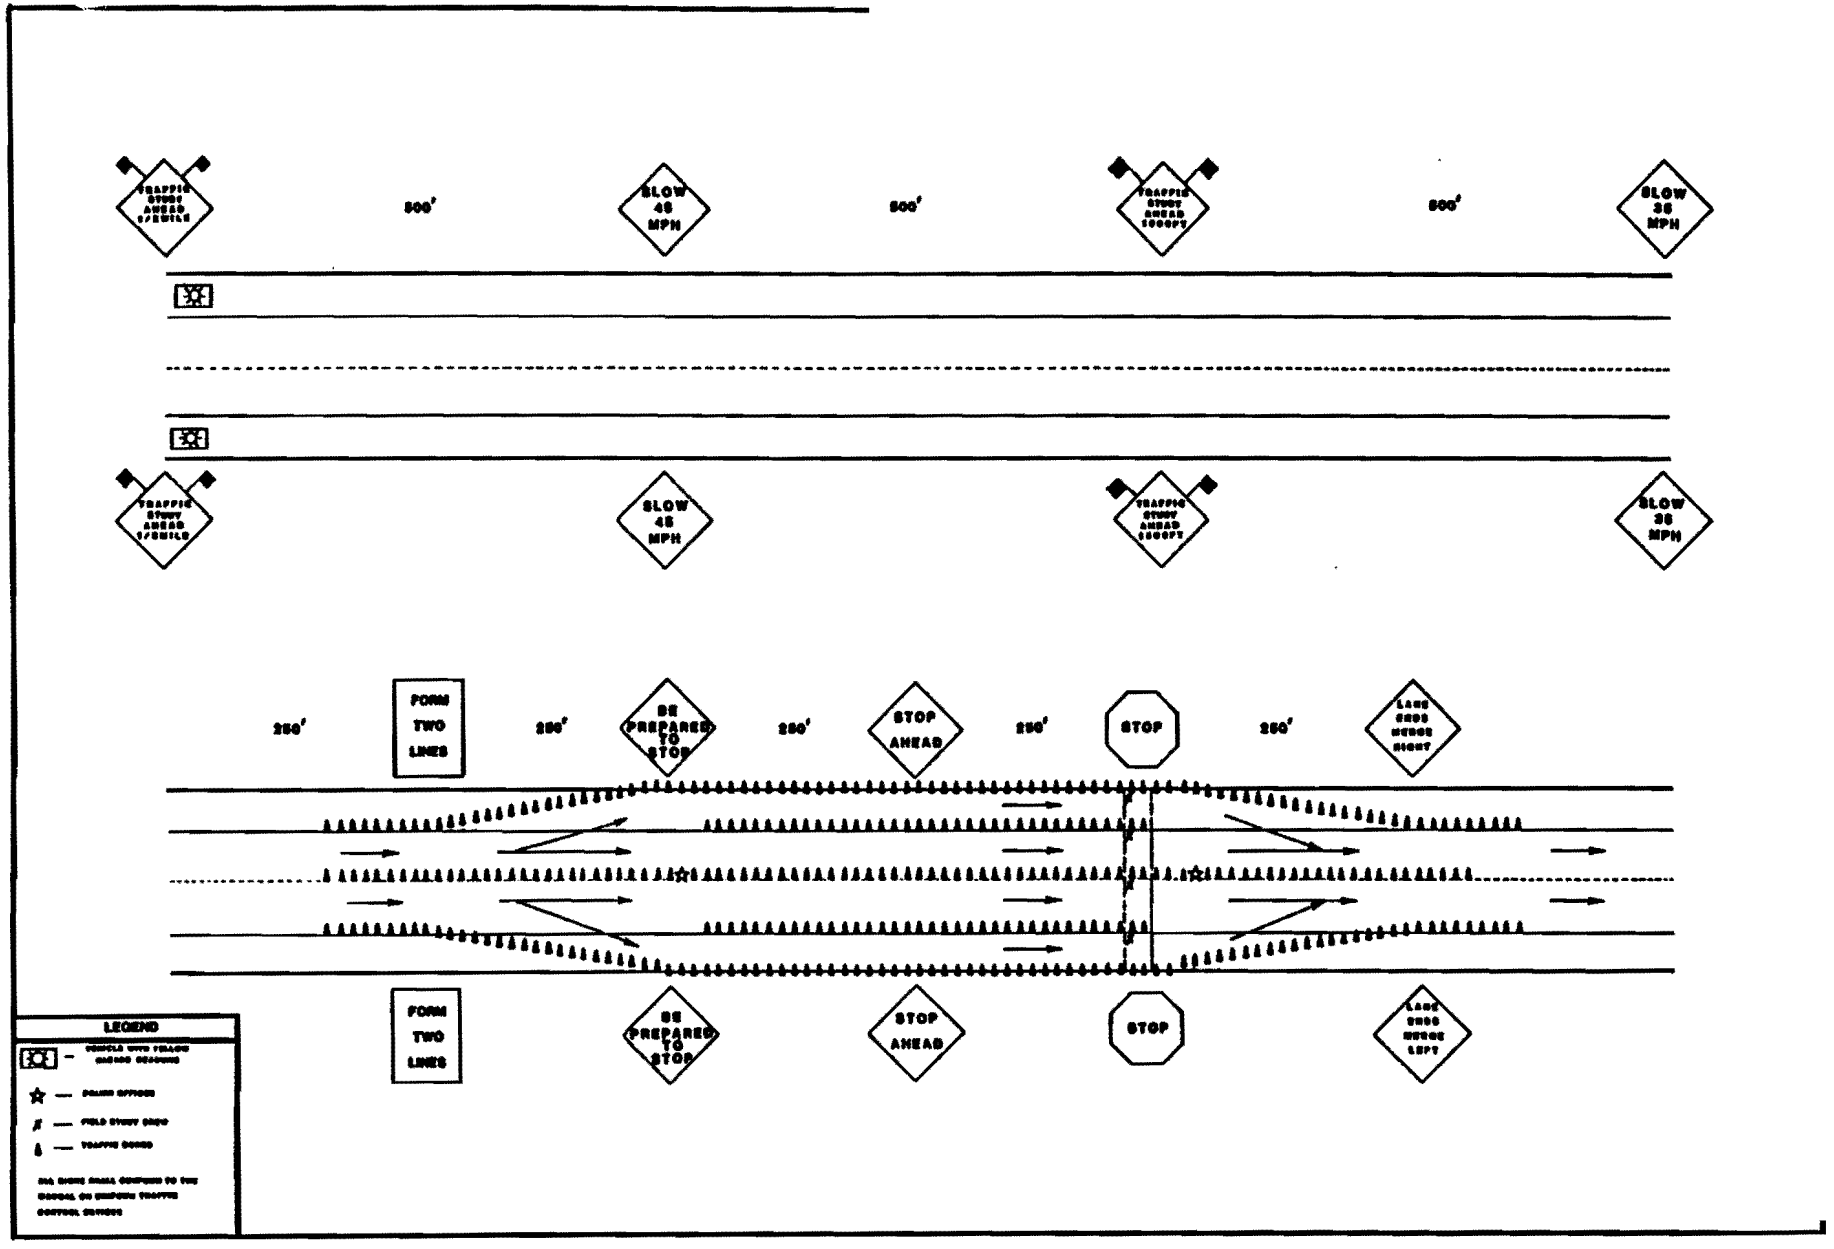

Figure 2. Recommended Setup for Interstate Highway Survey Stations.

perform field testing of station setup procedures at a low-volume, non-interstate station prior to full-scale implementation at higher volume stations.

3.3 TRAINING

A preliminary period of instruction should be held for supervisors and field survey crew members before the actual field work begins. This instruction period is very important. In general, the training session should be organized in a manner which will provide a thorough indoctrination as well as detailed instructions concerning the work to be performed. Specifically, the training program should address the following matters:

(1) Purpose of the travel surveys;

(2) Method to be used to obtain the travel data;

(3) Responsibilities of individual crew members;

(4) General work requirements, such as work hours, pay, travel requirements, equipment to be provided, etc.;

(5) Performance standards to be met, with particular emphasis on professionalism and observance of safety rules;

(6) Detailed discussion and explanation of the various survey and data collection forms; and

(7) Discussion of procedures to follow in resolving problems encountered in the field.

In training personnel to conduct the field work, it is recommended that the field supervisors be trained first. They can then assist in training the personnel who will be under their supervision in the field.

In scheduling and conducting the actual field surveys, it may be desirable to begin the surveys on the low-volume, non-interstate facilities. The survey crews can then work up to the more complex interstate stations.

3.4 MANPOWER REQUIREMENTS

A field crew for a high-volume survey station, such as might be established on I-35, should include the following:

3 Traffic recorders
5 Postcard distributors
2 Police officers
2 Traffic control specialists (for advance warning stations)
1 Crew chief
13 Persons/Crew/Station

Field crews for lower volume roadways in the corridor should include the following:

2 Traffic recorders
3 Postcard distributors
2 Police officers
2 Traffic control specialists
1 Crew chief
10 Persons/Crew/Station

The estimates for traffic recorder and postcard distribution personnel include provision for one substitute crew member for use when rests become necessary or in case of an emergency.

Assuming that the survey crews would need to be on-site for approximately 16 hours/day, the manpower requirements can be estimated as follows:

a) High-Volume Stations (I-35 and US 290)

13 persons x 8 stations x 16 hours/station = 1,664 hours

b) Low-Volume Stations

10 persons x 6 stations x 16 hours/station = 960 hours

In those cases where two survey stations are located immediately adjacent to one another, it may be possible to reduce the total manhour requirements by timing the opening and closing of stations in such a way that when one station is closed, the crew cAN transfer to the adjacent station and commence survey operations in the opposite direction. The practicality of this type of operation would need to be thoroughly examined prior to actual field implementation.

3.5 ESTIMATED COSTS AND WORK COMPLETION SCHEDULE

Tables 14 and 15 summarize estimated study costs and work completion schedules. The costs and work schedules are for the seven bi-directional survey stations identified in

Section 3.1.2 and are based on current TTI salaries, overhead rates, and projected manpower availability. These estimates include provisions for conducting license plate readings at the survey stations for the purpose of checking by zip code for possible biases in survey responses. This independent accuracy check would cost approximately $4,500.

The cost and work schedule estimates shown in Tables A-14 and A-15 do not include the suggested special nighttime truck survey. Since it is not possible to identify precisely how this special survey should be conducted, only some very preliminary estimates can be presented at this time. Assuming that roadside interviews could be conducted at the two check-stations on I-35, approximately three to four interviewers per station would be required. Assuming that the truck interview stations would operate 14 hours per day and that a total of approximately 1,200 interviews could be completed (See Table A-6), the data collection and analysis phases of the study could be completed at a cost of approximately $5,000 (this estimate does not include DPS expenses incurred in operating the check-stations during the survey period).

Table A-14. Estimated Study Costs

Item	Estimated Cost
DIRECT COSTS	
Salaries/Wages	$34,000
Supplies	4,000
Operating Expenses	
Travel	6,500
Phone	600
Fringe Benefits (15% Salaries & Wages)	5,100
Postage	11,000
Reproduction	600
Other	300
Equipment Rental	
Computer	1,500
Contract Labor	
Police Officers	6,500
TOTAL DIRECT COSTS (TDC)	70,100
INDIRECT COSTS (7% TDC)	4,900
SERVICES/EQUIPMENT PROVIDED BY SDHPT	-0-
TOTAL STUDY COSTS	$75,000

Table A-15. Estimated Work Completion Schedule

Study Phase	Estimated Completion Schedule
Pre-Planning	6 weeks
Field Survey	4 weeks
Data Processing	6 weeks
Data Analysis/Report Preparation	8 weeks
Total	24 weeks

SAMPLE SURVEY FORMS

SAMPLE SURVEY FORM

AUSTIN/SAN ANTONIO ORIGIN-DESTINATION STUDY

Dear Motorist:

Your help is needed in a special study being conducted on roadways between Austin and San Antonio to determine which improvements, if any, are the most feasible and most economical to implement.

The study has the objective of providing the traveling public with a safer and more efficient transportation system. However, in order to develop a better transportation system, it is first necessary to gain information on existing travel patterns. The results of this study will have direct application to any improvements considered on roadways between Austin and San Antonio.

Your cooperation and timely return of the completed questionnaire to this office will be appreciated. Information provided by you will be kept confidential. Only a summary of the results will be available for review.

If you have any questions concerning the questionnaire please call (phone no.).

The following questions concern the trip being made at the time you received this questionnaire. If you have received more than one questionnaire, please complete and return each questionnaire. Please accept our apology for any inconvenience our survey may have caused you.

---

1. Type of vehicle?
   Passenger Car☐ Pickup☐ Van☐ Other Truck☐

2. Purpose of trip today?
   Work☐ School☐ Shopping☐ Recreation☐ Other☐

3. Where were you coming from when you received this questionnaire?
   _____ ☐☐☐☐☐
   Street Address City Zip Code

4. Where were you going when you received this questionnaire?
   _____ ☐☐☐☐☐
   Street Address City Zip Code

5. How many people in vehicle (including driver)? _____

6. How many days per week do you make this trip?
   1☐ 2☐ more than 2☐ Other (please specify) _____

7. Any additional information on your trip that you think might be helpful to us would be appreciated. _____

Please detach and mail completed portion of the preaddressed questionnaire at your earliest convenience. Thank you.

Card No. XXXXX

APPENDIX A-3

NOTES ON CALCULATING SAMPLING VARIANCE AND PERCENTAGE ERROR OF O-D ESTIMATES

The results of an O-D survey obtained from a sample of vehicles passing a survey station can be expanded to obtain unbiased estimates of O-D interchange volumes to represent all vehicle, as explained in Section 3.1.6. The formula for expanding the survey results to the population, if the vehicles are randomly selected, is given by (6):

$$\hat{T} = (N/n)\ t \quad \ldots\ldots (1)$$

where:

$\hat{T}$ = number of vehicles in a universe of N vehicles which have a particular O-D

$\hat{T}$ = unbiased estimate of T

n = sample of vehicles chosen at random from N vehicles

t = number of vehicles in the sample which have the O-D

The sampling variance of $\hat{T}$ is given by (6):

$$\text{var}\ (\hat{T}) = [(N-n)\ N^2pq]/[(N-1)n] \quad \ldots\ldots (2)$$

where:

p = T/N

q = 1-p.

Percentage error in T which arises because of sampling variation is given by (6):

$$CV\ (\hat{T}) = [\{(N-n)/(N-1)\}(N/n)\ (1/T - 1/N)]^{1/2} \quad \ldots\ldots (3)$$

If the vehicles are selected by clusters or platoons, the formula used to expand to O-D survey results to represent all vehicles is given by (6):

$$\hat{T} = (G/g)\ t \quad \ldots\ldots (4)$$

where:

G = number of clusters in the population

g = number of clusters in the sample

t = number of vehicles with the O-D which are found in the sample

where t is given by:

$$t = \sum_{i=1}^{g} t_i$$

where t_i is the number of vehicles in the ith cluster (i = 1, 2, ..., G) which have the specified O-D.

The sampling variance using cluster sampling is given by (6):

$$\text{var}\,(\hat{T}) = [(G-g)/(G-1)]\,(G^2/g)\,\text{var}\,(t_i) \quad \ldots\ldots\ (5)$$

$$\text{where var}\,(t_i) = (G-1)/[G(g-1)] \sum_{i=1}^{g} (t_i - T/g)^2 \quad \ldots\ldots\ (6)$$

The percentage error in T which arises because of sampling variation in cluster sampling is given by (6):

$$CV\,(\hat{T}) = [\{(G-g)/(G-1)\}\,(G^2/g)\,\text{var}\,(t_i)/T^2)]^{1/2} \quad \ldots\ldots\ (7)$$

APPENDIX B
USER DOCUMENTATION: RI2-TLOG

Glossary Field Name	Description and Data Characteristics	Code Chart Name
ADM-SYS	Administrative System	Administrative System
ADT-C-YR	Annual average daily traffic, current year.	
ADT-YR1	AADT for one year prior to the current year. For example, if year of current year (YR-C-ADT), contains '73', this field will contain the ADT for 1972.	
ADT-YR2	AADT for two years prior to the current year.	
ADT-YR3	AADT for three years prior to the current year.	
ADT-YR4	AADT for four years prior to the current year.	
ADT-YR5	AADT for five years prior to the current year.	
ADT-YR6	AADT for six years prior to the current year.	
ADT-YR7	AADT for seven years prior to the current year.	
ADT-YR8	AADT for eight years prior to the current year.	
ADT-YR9	AADT for nine years prior to the current year.	
ATHWLD-A	Percent tandem axles in the average 10 heaviest wheel loads.	
ATHWLD-W	Average 10 heaviest wheel loads (in hundreds of pounds).	
BASE-TYP	Base type will be coded for all highways except Type of Base Status O. (This field will be zero filled for Status 0.)	
BEG-M-PT	Beginning milepoint will always be coded to 1/1000 mile. (Right-justified with lead zeros.)	

Glossary Field Name	Description and Data Characteristics	Code Chart Name
CITY-NUM	City number if this section of highway is in a city; otherwise this field will contain zeros. This is the census bureau city number with one digit added to the low order end.	City Number Table
CLASS	Maintenance Class Code.	
CON-LINK	Interstate Travelway Flag (Zero = Not IH Travelway, 1 = IH Travelway).	
CONTROL	State Highway Department Control Number, right-justified with lead zeros.	
COUNTY	THD county number right-justified with lead zeros.	THD County Name Table
D-YR	Design year. This will normally be 20 years after "Current Year." For design year 1992, this field will contain '92'.	
DCCSKEY	Entire record key (District-County-Control-Section-Beginning Milepoint).	
DHV	DHV = (ADT)(K)(D)(1+T)E_t - 1)) = 30th highest hourly volume for the design year Where T = % trucks in DHV/100 Et = Passenger car equivalents (2.0 for 2 lane facilities) (+2.5 for 4 lane facilities)	
DIR-DIST	Directional distribution in DHV. (This field will contain the percent of ADT in the direction of heaviest flow.)	
DISTRICT	THD District number right-justified with lead zeros.	
END-M-PT	End milepoint will always be coded 1/1000 mile (right-justified with lead zeros).	
EST-ADT	Estimated design year annual average daily traffic.	

Glossary Field Name	Description and Data Characteristics	Code Chart Name
EST-VM	Estimated design year vehicle miles (Daily) on this segment of road.	
FED-AID	This field contains the designated federal aid code. This field will indicate the federal aid that has been approved for this location, either existing facility or proposed location.	Federal-Aid System
FED-RES	If this section is located within a reservation, this field will indicate the type of reservation.	Reservation
FLEX-K	Number of 18-KIP wheel load applications in one direction in thousands (flexible pavement analysis).	
FILENUM	File number will indicate the file from which this record was obtained. Only File-1 (RI2-TLOG) will be available to RIS.	
FUNCT-CL	1980 Functional Classification of this link.	1980 National F.C. System
HWY-DESN	Highway Design Type. This field indicates the number of roadways, direction of traffic, and the number of frontage roads. This field will be zero filled if Highway Status = 0. FAU routes over one-way streets will not be combined as a pair. Each street will be logged and coded as a separate route. This file does not contain frontage road data except for the number of frontage roads as depicted by the appropriate Hwy design code.	Highway Design
HWY-NUMB	Designated Highway Number. For FAU routes, the FAU route number will be coded. This field will be right-justified with lead zeros.	

Glossary Field Name	Description and Data Characteristics	Code Chart Name
HWY-STAT	Highway Status Code 0 - Projected/Not Maintained. A proposed route where no public facility exists. Milepoints 50.000 and higher will be used. Code 1 - Under Maintenance. Existing facility signed as a highway. Code 3 - Under Construction, State Maintained Unit 1 (Grading and Structures) project is completed and accepted for maintenance on section of highway where there was no existing State route. Should the usual use of milepoints create duplicating milepoints in a control and section, milepoints in the 50.000 and higher category will be used. Status-3 projects are not open to traffic. Code 4 - A Metropolitan Highway, a Federal-Aid Route, or a proposed highway route over an existing facility under local maintenance.	
HWY-SYST	Designated Highway System. This field will be "00" for FAU Routes that are not designated by the Highway Commission.	Highway System
INCRFACT	20-year ADT increase factor (recorded as XX.XX percent).	
K-FACTOR	Percent the design hour is of the 24-hour AADT (recorded as XX.X).	
LGTHSECT	Length of section to 1/1000 mile. This field is right-justified with lead zeros.	
MAINTSEC	Maintenance Section Number. This field will be zero filled for all Highway Status 0 and 4 routes.	
MP-DATE	Date (YYMM) of last milepoint change on this segment of road.	
NUMB-LN	Number of Main Lanes. This field will be zero filled for Highway Status 0. Right-justified with lead zeros.	

Glossary Field Name	Description and Data Characteristics	Code Chart Name
P-TRKADT	Percent trucks in AADT (Recorded as XX.X).	
P-TRKDHV	Percent trucks in design hour volume (recorded as XX.X).	
RES-LOAD	Restricted Load Limit. If restricted by commission minute, coded to nearest thousand pounds; zero filled if not restricted.	
RIGID-K	Number of 18-KIP wheel load applications in one direction in thousands (RIGID pavement analysis).	
ROAD-BED	Road-Bed width. This is the width of the main lanes and shoulders in feet, right-justified with lead zeros. This width includes continuous left-turn lanes, excludes other median types and frontage roads.	
ROW-WID	Right-of-way width in feet, right-justified with lead zeros. This field will contain zeros for unknown, or for Highway Status 0.	
SECTION	SHD Section Number.	
SHLD-TYP	Shoulder Type. Zero filled for Highway Status 0.	Type of Shoulders
SPEED-LT	Posted Speed Limit. Only the 65 MPH sections are identified at this time (code 9). Code zero ('0') field indicates unknown.	
SP-SYS	Special Systems. This field is used to code special funding categories in which some Highway segments fall (see HPMS Field Manual, Item 17).	Special Systems
SUR-COMB	Combination of two or more surface types (two types of asphalt will not be considered a combination). Field will be zero filled for Highway Status 0.	
SURF-TYP	Surface Type. (Field will be blank for main lanes only for Highway Status 0).	

Glossary Field Name	Description and Data Characteristics	Code Chart Name
SURF-WID	Surface Width. This is the width of the main lane driving surface in feet, right-justified with lead zeros. Frontage roads are not considered.	
TNWLGT8K	Total number of wheel loads greater than 8,000 pounds (to nearest thousand).	
TRUCKS	Trucks or commercial vehicles (see description in Highway Performance Monitoring System Field Manual, Item-20).	Truck-Com.
URB-RURL	Rural-Urban, 1980 Functional Classification.	1980 National F.C. System
URBAN-NO	Urban Area Number (FIPS) (Length-5, numeric)	
VEH-MI	Vehicle miles daily (current year) on this segment of road.	
YR-C-ADT	Year of current AADT. If 'ADT-C-YR' represents 1973 Annual Average Daily Traffic, this field will contain '73'.	

APPENDIX C

ECONOMIC AND DEMOGRAPHIC DATA AND FORECASTS FOR TEXAS COUNTIES*

*The computer files for the data in this chapter are available from the authors.

ECONOMIC AND DEMOGRAPHIC DATA AND FORECASTS

The data in this Appendix were developed by Woods and Poole Economics, Inc. These data were selected for use in this Guide because they are more comprehensive than similar local data bases. As discussed below, the Woods and Poole data are generally consistent with locally developed data bases.

Table C-1 presents a comparison of state population forecasts as developed by the Texas State Data Center (SDC) and by Woods and Poole (W&P), Inc. As shown in Table C-1, the W&P forecasts are comparable to the middle-range forecasts developed by SDC.

Table C-1. Comparison of Texas Population Forecasts.

Source	State Population (1000's)				% Change 1990-2010
	1990	1995	2000	2010	
SDC					
0.0[a]	17400.29 (2%)[d]	18229.83 (3%)	19052.86 (4%)	20895.10 (7%)	17%
0.5[b]	17809.29 (-1%)	19215.66 (-3%)	20682.02 (-4%)	23999.09 (-7%)	26%
1.0[c]	18226.86 (-3%)	20257.27 (-8%)	22460.43 (-13%)	27598.05 (-23%)	34%
W&P	17682.34	18721.42	19914.82	22478.70	21%

[a] Assumes net migration is zero.

[b] Assumes rates of net migration one-half those of the 1970s. This represents SDC's "most likely" growth scenario.

[c] Assumes net migration rates of the 1970s (period of very rapid growth).

[d] (X%) denotes % difference (W&P vs. SDC)

The following information was taken from
Woods and Poole Economics, Inc., Washington D.C.

I. BACKGROUND AND STUDY OBJECTIVES

BACKGROUND

The Texas State Department of Highways and Public Transportation (SDHPT) presently uses trip rates developed in a 1973-75 study (1) to estimate the trip generation potentials of proposed new land uses in rural highway corridors. These estimates are used to adjust forecasts of future traffic volumes which are developed for the Department's various rural highway improvement projects.

The Texas Transportation Institute (TTI) has been asked to review the Department's current procedures for adjusting rural highway traffic forecasts to account for proposed land use changes and to formulate specific recommendations for implementing any improvements and/or modifications which may be needed in these procedures. Based on discussions with analysts in the Department's Traffic Analysis Subsection, the primary focus of this investigation is on the following two basic concerns:

(1) Temporal stability of trip rates. The trip rates used by the Department were developed from 1973 to 1975, and the current validity of these rates has been questioned.

(2) Applicability of trip rates to rural land uses. The trip rates currently used by the Department are primarily based on urban and suburban land uses. The Department is concerned about the applicability of these rates to rural land uses.

This Technical Note presents the findings and recommendations resulting from the investigation of these basic concerns.

STUDY OBJECTIVES

The objectives of this Technical Note are:

(1) Conduct a literature review to identify sources of trip generation data and studies concerning the temporal and geographic stability of these data;

(2) Assess current Department practice relative to the state of the art;

(3) Develop specific recommendations for upgrading current Department practice, if necessary;

(4) Prepare detailed instructions for implementing any new or revised procedures; and

(5) Document the results of this study in a Technical Note.

II. LITERATURE REVIEW AND ASSESSMENT OF CURRENT PRACTICE IN TEXAS

SOURCES OF TRIP GENERATION DATA

In the 1960s, most urban areas (population >50,000) conducted home interview travel surveys in which data on trip generation rates were collected. The trip generation rates (or, more specifically, trip production rates) developed from these surveys (and subsequent updates) were generally expressed at the household level in the form of cross-classification or regression models. Models for estimating nonresidential trip generation are typically based on the classification and intensity of land-use activities at the attraction end of the trip. These trip attraction models are commonly cross-classification or regression models which relate trip-making per acre or per square foot for a limited number of generic land-use classifications (manufacturing, transportation, commercial, public buildings, and public open space) and on distance from the central business district.

The trip production and attraction models outlined above are intended for use at the urban area or regional level. As a result, the trip rates employed in these models, while appropriate for use in long range comprehensive planning, lack the accuracy, level of detail, and sensitivity typically required for site-specific traffic impact studies. As an example, in order to apply the household trip rates derived from home-interview surveys to residential traffic impact studies, it is often necessary to adjust these rates to account for the trips by nonresidents (visitors, service vehicles, etc.).

The trip generation rates needed in site-specific analyses are typically derived from driveway (ground) vehicular counts conducted at individual traffic generator sites. In this approach, manual counts or automatic traffic recorders are used to collect peak- and 24-hour traffic data on the driveways of the special generator and the adjacent streets. The resulting traffic data, along with other site information such as dwelling units, gross floor area, number of employees, and acres of land, are utilized to estimate vehicle trip rates per dwelling unit and/or other independent variables. These rates, when applied to proposed land uses, result in estimates of future daily and peak hour trips.

A large number of these ground count-based trip generation studies have been conducted over the past 25 years. A recent study conducted for the Federal Highway Administration (FHWA) identified over 500 references to locally developed trip generation

rates (2). Only about 70 of these references, however, were found to contain "comprehensive" trip generation data (i.e., trip rate data for the range of land uses most frequently addressed in site-specific traffic impact studies). These locally developed trip generation data bases provide a wealth of information which, if properly aggregated, can be used: (1) to supplement limited local data on trip rates for specific land uses, or (2) as the sole basis for trip generation analysis in those cases where local (site-specific) data are unavailable. In these situations, the Institute of Transportation Engineers (ITE) **Trip Generation** report (3) is generally considered the standard reference manual on trip generation. The rates in the ITE **Trip Generation** report represent weighted averages from nearly 2,000 individual studies conducted throughout the United States since 1966. The ITE trip rates have been developed for the average weekday, Saturday, and Sunday; for the peak hours of the generator; and for the one hour when the adjacent street traffic is at its peak (3). Updated editions of the ITE Report are periodically published to incorporate data from new studies and analysis of additional land-uses and building types.

The trip generation rates derived from local ground count-based studies should be the primary source for the trip rates used in site-specific traffic impact analyses. In the absence of local data, and in those cases where the local data do not reflect variations in trip rates by time-of-day, secondary data sources should be consulted.

It is the recommendation of this study that the Department adopt the ITE **Trip Generation** report as the secondary data source for rural highway trip generation analyses. The Department should continue to use the **Special Traffic Generator Study** (1) as the primary source for trip rate information. The basis for this recommendation is developed in detail in subsequent sections of this Technical Note.

STABILITY AND TRANSFERABILITY OF TRIP RATES

The data base used in the ITE report extends back to the 1960s, and there has been "concern that the data collected before the first serious energy crisis (1973) may differ from the data collected after the energy crisis"(2, 3). In 1985, the FHWA analyzed the ITE trip generation data base and concluded:

> "Based on statistical tests such as t-test and f-ratios, it was concluded that there were no significant differences between the mean trip rates of older data (pre-1973) and new data (post-1973) for all land uses analyzed."(2).

With respect to the geographic stability and transferability of trip rates, only the single-family residential trip rates in the Department's **Special Traffic Generator Study** (1) have been classified by area type (i.e., residential density). These trip rates are shown in Table D-1. The **Special Traffic Generator Study** notes that because the variation exhibited by these rates is "greater than statistically desired," their use should be restricted to those situations where more detailed information such as average family income or family size is unavailable. As an indication of the statistical significance of the apparent differences in the trip rates displayed in Table D-1, note that the 95% confidence intervals (mean ± 2 std. dev.) for the urban and rural rates overlap considerably.

Table D-1. Residential Trip Rates by Residential Density (Texas)

Density Classification[a]	Veh. Trips/D.U.		Person Trips/D.U.	
	Mean	Std. Dev.	Mean	Std. Dev.
Urban	12.7	2.4	20.3	4.8
Suburban	9.4	2.1	14.7	3.5
Rural	7.6	2.5	13.6	5.2
Resort	5.4	0.6	7.8	1.1

[a] Urban is defined as those developments within the "core" of the urbanized area and therefore close to central activity centers. Suburban includes those areas located in the fringes of the city and are characterized as having easy access to some activity centers, primarily for convenience shopping. Rural, while within the urban area limits, is classified as those areas usually separated from the city by a considerable distance and are not close to any significant activity center. Resort are areas defined as those built primarily near recreational activity areas (mostly lake resorts) and are generally considered "second homes."

Source: **Special Traffic Generator Study** (1).

In addition to the limited data in the Department's **Special Traffic Generator Study**, the literature search revealed only two other studies which addressed the differences in rural and urban trip rates. Unfortunately, these two studies provide somewhat contradictory evidence concerning the transferability of trip rates from one area type to another. Moreover, these two studies focus on estimating trip rates at the individual household level; i.e., the focus is on the household trip production rates used in regional travel demand modeling. As a result, the relevance of these studies to the objectives of this Technical Note is more illustrative than prescriptive.

In a 1984 study, Brunso and Hartgen analyzed person trip rates determined in a statewide telephone survey of 1,500 New York State residents 18 years of age or older (4).

The results of their study are summarized in Table D-2. Brunso and Hartgen concluded that:

> "There were no significant differences in average trip rates between upstate and downstate New York, or between urban, suburban, small town, or rural areas of the state. Trip rates vary with income, employment status, sex, number of household vehicles, and presence of children. It was concluded that trip-generation rates are largely transferable between geographic areas, if demographic differences are accounted for . . . " (4).

Table D-2. Average Person Trips per Day by Area Type (New York State)

Region	City	Suburban	Small Town	Rural	Total
Upstate					
Avg. trips	2.7	3.1	2.6	2.6	2.7

Source: "An Update on Household-Reported Trip-Generation Rates"(4).

A study conducted in New Jersey evaluated the interregional stability of household trip generation rates derived from a 1986 home interview survey of approximately 2,800 households (5). The resulting trip rates by trip purpose and area type are summarized in Table D-3. The study results, while inconclusive, suggest that:

> "There is some evidence . . . that trip rates vary significantly by area type, with urban rates being lower than suburban and rural rates. [See Table D-3]. This variation results from the higher tendency to make walk trips in large urban areas. The small sample associated with urban land uses [sample size was not specified] made it difficult to draw strong statistical conclusions in this regard, however." (5).

Table D-3. Variation in Household Trip Rates by Trip Purpose and Area Type (New Jersey)

Trip Purpose	Area Type				All Households
	Urban	Suburban	Rural	Open Rural	
HBW	2.17	2.25	2.30	2.30	2.25
HBNW	2.72	3.24	3.13	3.70	3.17
HBSCH	0.57	0.76	1.26	0.78	0.85
NHB	1.66	1.56	1.55	1.83	1.57
TOTAL	7.13	7.82	8.24	8.61	7.84

Source: "Interregional Stability of Household Trip Generation Rates from the 1986 New Jersey Home Interview Survey" (5).

The results of the New York and New Jersey studies do not provide conclusive statistical evidence concerning the significance of any differences which might exist in household trip production rates by area type (e.g., urban vs. rural). In terms of the objectives of the present investigation, it appears that if any studies have been conducted concerning the more germane question of whether trip attraction rates vary by area type, the results have not been made a part of the relevant body of literature.

In the absence of any objective evidence, the analyst must rely on subjective assessments of the impacts of possible geographic variations in trip attraction rates. For example, if it is assumed that the basic site, personnel, and market area requirements of specific categories of commercial and manufacturing land uses are more or less fixed, then the level of activity, and the resulting trip generation potential, should be largely independent of geographic location. Another way of stating this argument is that commercial and manufacturing firms typically will not locate in areas which do not meet certain minimum labor force and market area population (i.e., trip generation) criteria.

Another subjective consideration concerns the practical implications of any geographic variation which might exist in trip attraction rates. Briefly stated, it would appear that any geographic variation which might exist in trip generation rates are not likely to be of sufficient magnitude to alter basic design decisions involving most low volume rural highway improvement projects.

Based on the results of the literature review and the subjective considerations outlined in the preceding paragraphs, it is the recommendation of this study that the

Department continue to use the **Special Traffic Generator Study** as the primary source for trip rates in traffic impact studies of proposed land use changes in low volume rural highway corridors. Limited evidence from a previous study (2) suggests that average trip rates have not changed significantly since 1973. At this time, there does not appear to be any conclusive evidence that rural trip rates are substantially different from urban or suburban trip rates. Residential trip rates appear to vary more with income, employment status, household size and vehicle ownership rates, than with area type. From a practical standpoint, it does not appear likely that the magnitude of any geographic or temporal differences that might exist in trip rates would be sufficient to alter basic design decisions concerning most low volume rural highway projects. As recommended in the previous subsection of this Technical Note, the Department should use the ITE **Trip Generation** report as the secondary data source for rural highway trip generation analyses.

COMPARISON OF TEXAS AND ITE TRIP GENERATION DATA

The two basic recommendations put forth in the preceding subsections of this Technical Note suggest that the only change needed in current Departmental practice is the adoption and use of the ITE **Trip Generation** report as a supplement to the Department's **Special Traffic Generator Study**. A brief comparison of these two data sources is presented below. The intent of this comparison is to highlight differences and similarities in the two data bases and to provide some general guidelines for selecting the appropriate data base for a particular problem. Detailed instructions for using the ITE data are presented in Chapter III of this Technical Note.

A summary and comparison of the land-use categories and independent variables in the ITE and Texas trip generation data bases are presented in Table D-1 (Exhibit D-1). In terms of the number of land-use categories for which trip rates have been developed, the ITE data base is much more extensive than the Texas data. The ITE data present trip rates for 90 land uses, while the Texas data represents only 20 uses.

The Texas data represent daily (24-hour) trip rates and are reported for vehicle- and person-trips. The ITE data represent vehicle-trips only, but the trip rates are reported for the following time periods (3):

(1) Average weekday;

(2) Weekday peak hour of adjacent street traffic;

(3) Weekday peak hour of the generator;

(4) 24-hour Saturday trips;

(5) Saturday peak hour of the generator;

(6) 24-hour Sunday trips; and

(7) Sunday peak hour of the generator.

Table D-4 presents a comparison of the ITE and Texas trip rates for those land uses and independent variables which are common to both data bases. While the percent differences in trip rates appear to be substantial in some instances, the absolute differences are, in most cases, probably within the expected error ranges of the respective data bases.

Given the differences which exist in terms of land-use definitions and sample size considerations, the trip rates in the ITE and Texas data bases appear to be reasonably consistent. As long as the analyst recognizes the limitations inherent in these data, and exercises his/her professional judgment in the development and application of trip rates, the ITE data can greatly expand both the range and level of detail in the trip generation data base available to the Department for use in traffic impact analyses in low volume rural highway corridors. The ITE data can be particularly useful in estimating trip rates for land uses which are not represented in the Department's Special Traffic Generator Study, and/or in accounting for time-of-day/day-of-week variations in trip rates. In those cases where the necessary trip rate data are available from the **Special Traffic Generator Study**, the ITE data can be used to confirm the validity of the local data, or as the basis for developing a range of trip rates for use in various sensitivity analyses.

Table D-4. Comparison of ITE and Texas Trip Rates[a]

Land Use	Average Daily Trip Rate (Vehicles)		Percent Difference
	ITE	Texas	
Port and Terminal			
Waterports	11.9/Acre	14.3/Acre	+20%

[b] Representative values for 400,000 sq. ft. regional shopping center. Texas data distinguish between regional and neighborhood shopping centers.

III. INSTRUCTIONS FOR USING THE ITE TRIP GENERATION REPORT[1]

DATA FORMAT

A sample of the ITE **Trip Generation** report display format is shown on the following page. The data summaries for each land-use or building type are preceded by a brief introduction containing the following basic information: (a) description of the land-use or building types for which the trip rates are applicable; (b) an overview of trip characteristics of each land use; (c) average weekday transit trip ends, if available; (d) factors for adjusting the average trip rates to account for a limited number of site-specific physical and demographic factors; (e) data limitations; and (f) data sources. It is recommended that the analyst carefully read this introductory material prior to using the ITE trip rates.

For the majority of ITE land uses, the trip rates do not vary with the size of the independent variable. For example, when calculating trip generation for a residential subdivision of single-family detached houses, the trip-making rate is constant, whether the subdivision has 100 homes or 500 homes. These constant rates are displayed throughout **Trip Generation** report for each land use, each independent variable associated with that land use, and for different time periods (average weekday traffic, weekday peak hour of adjacent street traffic, weekday peak hour of the generator, average Saturday traffic, Saturday peak hour of the generator, average Sunday traffic, and Sunday peak hour of generator).

Unlike the trip generation rates for other land uses, the rates for general office buildings and shopping centers vary with the size of the independent variable. The rates decrease as the buildings increase in size. Therefore, the standard trip generation rate tables (see following page) are not presented for these land uses. Instead, regression equations and graphs indicating the trip rates as a function of building size are presented.

Trip Generation provides the user with three methodologies to assist in determining the average trip rate of a land use or building:

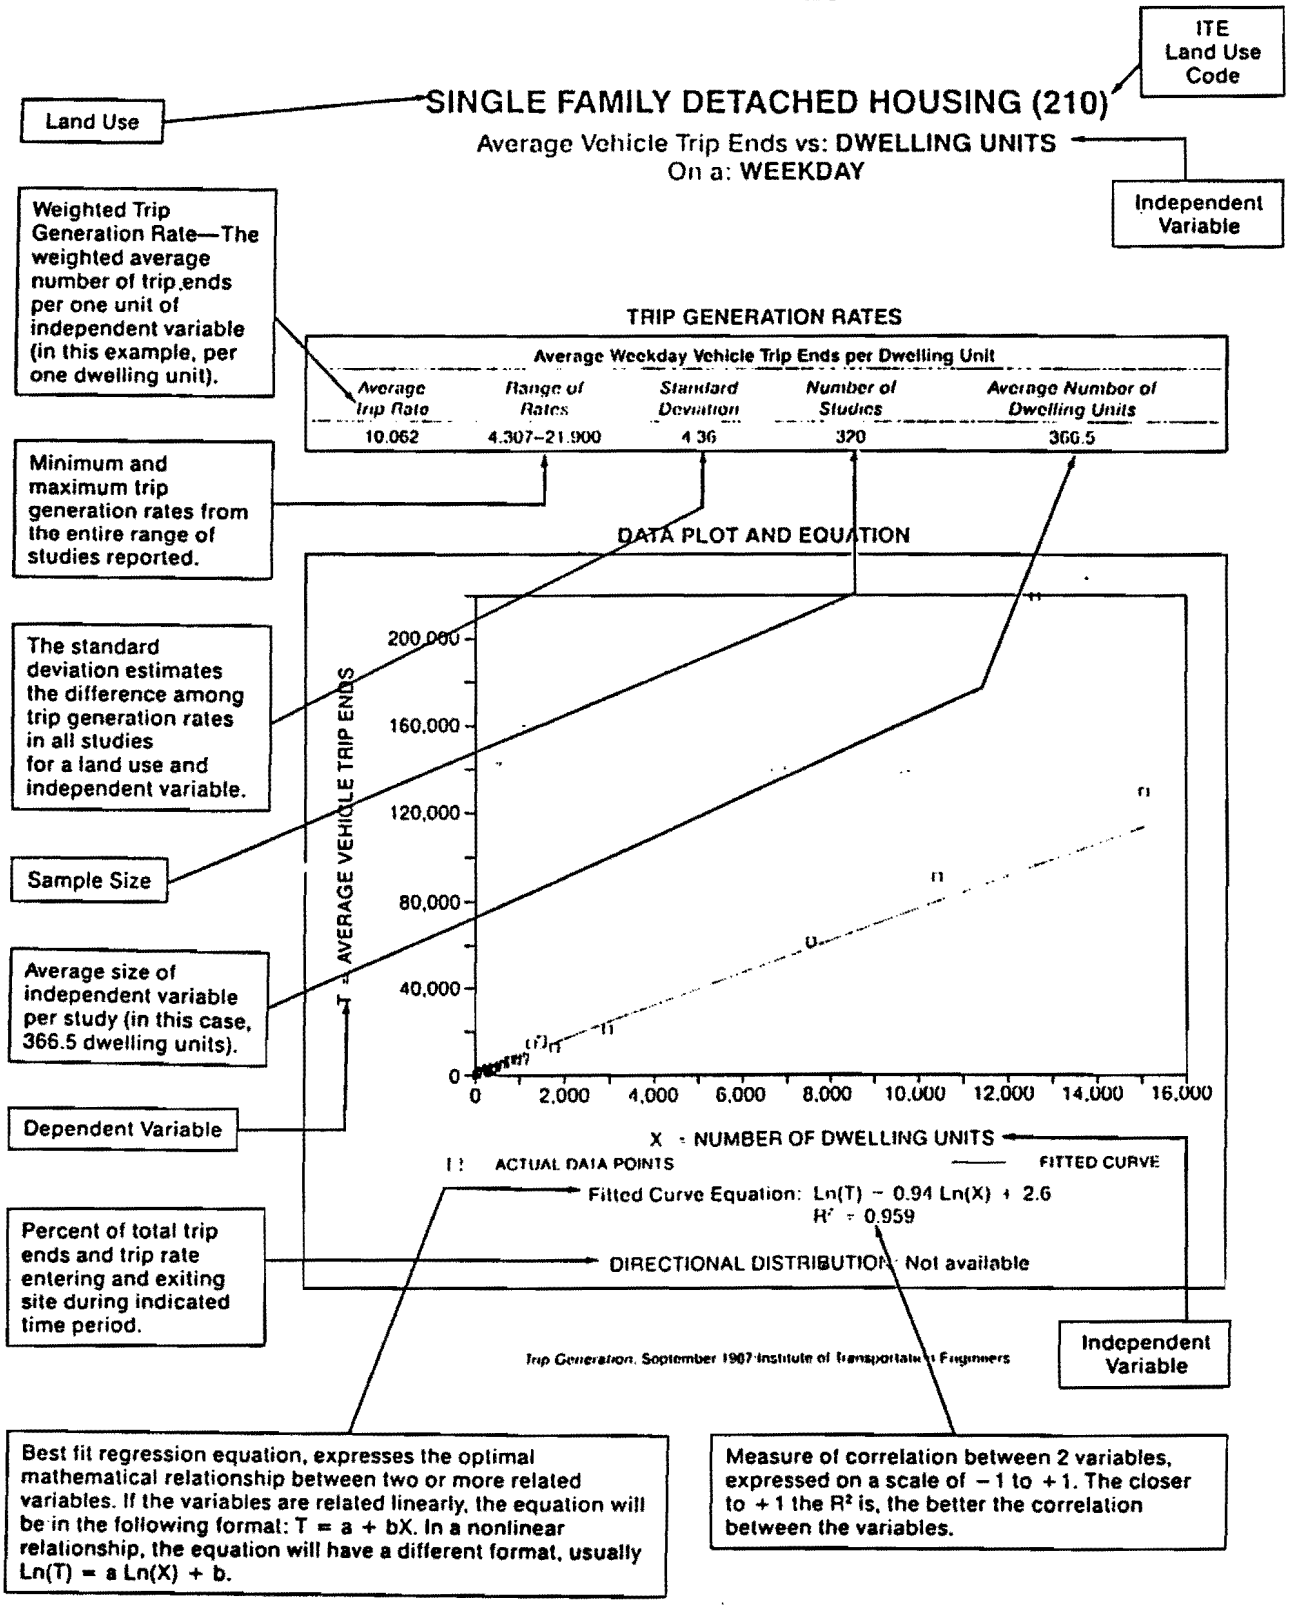
(1) Weighted trip generation rate, or the number of weighted trip ends per one unit of the independent variable (e.g., per employee or per 1,000 square feet).

---

[1]Much of the material in this chapter comes directly from **Trip Generation** (3).

Sample Page from

ITE Trip Generation



Note: See Exhibit D-2 for definitions of key terms.

Source: **Trip Generation** (3).

(2) A plot of the actual trip ends versus the size of the independent variable for each study.

(3) Regression equation of trip ends related to the independent variable.

DATA LIMITATIONS AND LEVEL OF CONFIDENCE

The data used to calculate the ITE trip rates have been collected with automatic counters. The counts of vehicular traffic entering and exiting a site vary in duration from one weekday to seven days. These counts were designed to cordon the site and do not include through traffic. They were made on driveways of sufficient length to avoid double counting of turning vehicles. In some cases, counts were nondirectional and therefore did not distinguish entering from exiting vehicles. Manual counts supplemented some of the automatic counts to obtain vehicle occupancy and classification, to check the reliability of the automatic counts, and to obtain directional counts during peak periods where a nondirectional automatic count was being conducted. In other cases, only manual counts were conducted during peak periods. Therefore, all data in **Trip Generation** represent vehicle trip rates rather than person trip rates.

Because some of the data represented only average weekday volumes, some nondirectional peak hour volumes, and some directional peak hour and average weekday volumes, separate analyses were made for each type of measurement to obtain rates for various time periods of the day or week. Therefore, in most cases, the peak hour entering and exiting rates in the raw data did not equal the total two-way rates. However, adjustments have been made to the average entering and exiting rates so that the rates presented in **Trip Generation** equal the total two-way rates. The entering and exiting rates for the minimum or maximum rates, however, have not been adjusted; they indicate the actual rates. Therefore, the average adjusted entering and exiting rate sometimes may be higher than the maximum measured rate because of this adjustment procedure.

The average trip rates presented in **Trip Generation** are all calculated on the basis of a weighted average trip rate. The weighted average is used rather than the average of individual rates because of the variance within each data set or generating unit. The following three tools are provided in **Trip Generation** to give the user an approximation of the variance of the data (see the sample page from **Trip Generation** in preceding section):

(1) A plot of the actual number of trips versus the size of the independent variable for each study. The numbers represented on the plots are not trip generation rates; they are the actual number of trips, plotted against an independent variable.

(2) Standard deviation for the weighted average trip rate for all land uses with more than 20 studies or data sets. This provides the user with an indication of the difference between studies or data sets and the difference between generating units within a study or data set.

(3) Regression equations of trip ends related to the appropriate independent variable and the R^2 value.

The basic limitation in the data used to develop the trip rates in **Trip Generation** is the sample size of the counts at some generators. Additional data are needed for some generators to more accurately estimate the peak hour entering and exiting rates. Those trip rates which have been estimated from small samples display the following caveat: **"Caution - Use Carefully - Small Sample Size."**

Another reason for the variation exhibited by the ITE trip rate data is the different lengths of count periods and the time of the year the traffic volumes were counted. Daily and seasonal variations exist for most generators. In some cases, full-week counts were conducted to define the average weekday; in other cases, only a single day's count was obtained.

Finally, the rates summarized in **Trip Generation** are for vehicle trip ends only and do not include all person trip ends by mode. More data are needed for each building and land-use type to define vehicle occupancy rates and person trip generation rates by mode of travel. As a result, "users may wish to modify or adjust the [ITE] rates to reflect public transportation services, ride sharing, proximity to other developments that may reduce vehicle trip making through walking or combined trips, and special characteristics of the site or the surrounding area." General guidelines for these and other basic adjustments which may be needed are outlined in a subsequent section of this Note.

CHOICE OF GENERATION RATES

The use of the average ITE trip rates or the regression equations is applicable if the

generator is most likely to be "typical" in nature. If, however, there is evidence, such as from local data or through a market analysis, that the generator in question may be better or worse than average, the analyst must rely on professional judgment to select an appropriate trip rate. In those situations where there is some question as to whether the generator is "typical," it is recommended that the analyst assess the design requirements associated with a range of trip rates. In most cases, basic design requirements are not likely to change substantially over a wide range of trip rates.

The choice of trip rates for a specific time period is a function of the type of generator, traffic characteristics on the adjacent street system, and the purposes of the traffic impact analyses. The analyst is advised to examine the range of average rates for the different time periods to determine when the generator in question peaks in traffic flow and to define the relationship between the peak generation and peaking characteristics of the adjacent street system. For example, residential and general office developments share the same peak periods of the adjacent streets. However, some uses such as shopping centers, may have a considerable impact during the normal p.m. peak hour of the street system, but can have an even greater impact on Saturdays. Therefore, the analyst should analyze the generator for several time periods to determine the appropriate design requirements.

The ITE vehicle trip rates for most building or land-use types are provided for more than one independent variable. If the analyst is fortunate enough to be able to choose from among several independent variables, the first choice should be the variable with the best (i.e., largest) correlation coefficient. However, it is also important to check the sample size for each independent variable. In the case of two variables with similar correlation coefficients, the analyst should choose the variable with the larger sample size (3).

In those situations where the analyst has no choice concerning the selection of the independent variable, such as in the early planning stages of a development when only the size of the land parcel or the size of the building are known, some important independent variables can be estimated on the basis of other variables. For example, the amount of employment and parking can be estimated on the basis of gross square feet of building space. Therefore, gross square feet of building space would be the preferred variable. When little is known about the size of the generator except the size of the land parcel, the common land use densities can be used to obtain an estimate of the magnitude of an

independent variable with a higher correlation coefficient or a larger data base. ITE's **Trip Generation** and the Department's **Special Traffic Generator Study** both provide information on densities for common land-use and building types.

Generally, using acres of land as the independent variable is not recommended because the data base for this variable is the smallest and its correlation coefficient is usually the lowest. For industrial uses, it is recommended that the analyst use the information on employee densities per acre in **Trip Generation** or the **Special Traffic Generator Study** to estimate employment. Trip rates per employee can then be used to estimate the trip generation potentials of the site in question. For office buildings or shopping centers, building sizes could be estimated from the size of the parcel and site trip generation expressed in terms of trips per 1,000 gross square feet or gross leasable square feet of building area.

ADJUSTMENT OF ITE TRIP RATES

The average trip rates and regression equations presented in **Trip Generation** are applicable to land-use and building types which are "average" in nature. The definition of "average conditions" can be found in the introduction which precedes the trip rate data summaries for each land-use code in **Trip Generation**. Because there can be as wide a variation in trips generated within some land-use categories as there is between different land uses, the analyst must recognize and, to the extent feasible, account for site conditions which may be better or worse than average. **Trip Generation** provides adjustment factors for average weekday trip rates for selected residential land uses based on demographic characteristics. For example, the adjustment factors shown below for single-family detached housing are to be added or subtracted from the average weekday trip rates using dwelling units as the independent variable. Any combination of adjustment factors may be applied to the trip rate. Peak hour trip rates can be adjusted by the ratio of the average weekday adjusted trip rate to the average weekday trip rate. Comparable adjustment factors are also presented for several other residential land use categories.

Characteristic	Adjustment Factor
Household size	
1 - 2	-3.4
2 - 3	-1.8
>3	0.0
Vehicles Owned	
0 - 1	-1.5
1 - 2	0.0
>2	+2.9
Density (DU/Acre)	
0 - 3	0.0
3 - 5	0.0
>5	-0.1

Trip Generation also describes a straightforward procedure for adjusting the ITE average trip rates to reflect the use of transit or other modes of transportation. Basically, the procedure involves converting site-specific data (or assumptions) on vehicle occupancy and transit utilization to vehicle trips and subtracting these trips from the average trip rates provided in the data summary tables.

The trip generation rates and equations in **Trip Generation** were derived from actual measurements of traffic on the driveways of the various land-use or building types. However, in some cases, the driveway volume at a generator is different from the amount of traffic added to the adjacent street system (3). This is because certain buildings such as retail establishments, certain restaurants, banks, service stations, and convenience markets attract traffic from the passing stream of traffic. Trip making where this phenomenon occurs can be broken down into the following three categories of trips (3):

(1) Primary trips

(2) Diverted linked trips

(3) Pass-by trips

A primary trip destined to a retail facility, for example, is made for the specific purpose of shopping. Such a trip would be characterized by a home-to-shopping-to-home pattern. A diverted linked trip or a pass-by trip is one in which the shopping destination,

in this example, is a secondary part of the primary trip, such as work-to-shopping-to-home. The diverted linked trip involves a route diversion from one roadway to another to reach the retail facility. The pass-by trip comes directly from the traffic stream passing the facility on the adjacent street system and does not require a diversion from another roadway.

The significance of pass-by trips is that they do not represent new traffic on the adjacent street system. For certain land-use and building types located in high volume travel corridors, failure to account for pass-by trips can result in over-estimation of the impacts of these generators on the adjacent street system. For buildings such as retail establishments, fast food/traveler-oriented restaurants, banks, service stations, and convenience markets located in heavily traveled corridors, it is essential that the pass-by trip phenomenon be recognized when examining the traffic impact of a development on the adjacent street system.

ITE's **Trip Generation** presents some preliminary guidelines, based on very limited data, for quantifying primary, diverted, and pass-by trips for the average weekday and Saturday. Most of these data are for shopping centers, though some data are presented for land uses other than shopping centers. The following regression equation is presented in **Trip Generation** for estimating pass-by trips as a percentage of total trips entering a shopping center during the average weekday (3):

$$T = 45.1 - 0.0225(A) \qquad (R^2 = 0.21)$$

where:

T = Pass-by trips as percentage of total weekday trips entering a shopping center

A = Square feet of gross leasable area (1,000s)

Using one or more of the adjustments outlined above may be necessary when applying the ITE trip generation rates. The need for/feasibility of applying these adjustments will depend upon the level of precision required in the traffic impact assessment and the level of detail in the information available to the analyst concerning the generator in question. In the absence of detailed data on the site characteristics and the surrounding area, use of the unadjusted average trip rates in **Trip Generation** should provide trip generation estimates which are sufficiently accurate for most rural highway planning studies.

IV. RECOMMENDED PROCEDURE FOR RURAL TRIP GENERATION ANALYSIS

OVERVIEW

This chapter presents a recommended procedure for adjusting rural highway traffic forecasts to account for proposed land-use changes. The procedure is a slightly modified version of the FHWA "Site Access Study Process" (6) and consists of the following seven steps. The technical considerations associated with each of these seven steps are described in the following subsections of this Technical Note:

(1) Compile Preliminary Data Collection and Study Design.

(2) Forecast Future Traffic without Proposed Land Use Change.

(3) Estimate Traffic Impacts of Proposed Land Use.

(4) Adjust Traffic Forecast to Account for Impacts of Proposed Land Use.

(5) Conduct Level of Service/Alternatives Analysis Using Adjusted Forecast.

(6) Develop Roadway Design(s).

(7) Document Findings.

RECOMMENDED PROCEDURE

The Department's process for conducting rural trip generation studies currently addresses the basic elements of the seven steps listed above. Therefore, the primary focus of the following discussion is on specific aspects of those steps where changes in current Department practice should be instituted, specifically in Steps (1), (3), and (4). The remaining steps are consistent with current Departmental practice and are treated in much less detail.

Step 1: Compile Preliminary Data Collection and Study Design

The objective of Step 1 is to compile a preliminary inventory of existing data which can be used in conducting the study. The results of this preliminary data collection activity will provide the basis for developing a basic study design which outlines the scope and level of detail of the traffic analyses. The basic study design should be discussed with representatives of the Departmental unit that has requested the traffic forecast(s) and/or impact study. This initial step in the procedure should focus on determining the availability

of, or feasibility of obtaining, the basic information listed below:

A. Traffic/Transportation Data

(1) Current traffic in the vicinity of the proposed land use (ADT, peak/design hour traffic, turning movement counts, vehicle classification, and occupancy data).

(2) Current level of service provided by roadways in the vicinity of the proposed land use.

(3) Proposed and programmed road/traffic operations improvements in the vicinity of the proposed land use.

B. Generator Site Data

(1) Proposed land-use or building type.

(2) Proposed site plans.

(3) Development program schedule/staging (year project will be fully developed/occupied).

(4) Characteristics of the generator (employment, number of DUs, floor area, parking spaces, etc.).

(5) Basic site access constraints/opportunities.

(6) On-site circulation, ingress/egress points.

The scope of a particular study will of course depend upon whether the analyses will be based solely on existing and readily available data or will be supplemented by the collection of additional data. The implications of the amount and quality of the data used in the analyses should be discussed with representatives of the unit requesting the study. The costs and responsibilities for any additional data collection efforts should also be discussed with these representatives.

Step 2: Forecast Future Traffic without Proposed Land Use Change

Forecasts of future traffic on the study area roadways should be prepared in accordance with standard Department practice. However, the analyst should review these forecasts and assess the extent to which they capture the effects of new developments in the corridor in question. Because traffic forecasts based on historical trends implicitly assume that these past trends, including land development trends, will continue into the future, the

analyst must assess the extent to which the proposed land-use change in question differs from the types of developments which have occurred in the corridor in the past. If the proposed land use is "typical" of past development patterns in the corridor, then the traffic forecasts probably represent, to some extent, the effects of the proposed development. If, on the other hand, the proposed land use differs substantially from past patterns in terms of its magnitude or nature, then the traffic forecasts will need to be adjusted accordingly (see Steps 3 and 4). No hard-and-fast guidelines concerning the need for these adjustments can be offered, and the analyst must rely upon personal knowledge of the study area and professional judgment to resolve this issue.

Step 3: Estimate Traffic Impacts of Proposed Land Use

The primary source for trip generation rates to estimate the impacts of the proposed land use is the Department's **Special Traffic Generator Study**. If trip rates for the proposed land use are not available from the **Special Traffic Generator Study**, or if a range of rates is desired, it is recommended that the analyst consult the ITE **Trip Generation** report. For guidelines concerning the selection of the appropriate independent variable(s) for the trip rates, the analyst is referred to the "Choice of Generation Rates" section of Chapter III of this Note. Depending upon data availability and the purpose of the analysis, the analyst may wish to adjust the average trip rates to account for site conditions which may be better or worse than average. Guidelines for making these adjustments are outlined in Chapter III of this Note. The trip rates and any adjustments should be applied to the generator as it will exist in the traffic design year. (This is an issue only in those cases where the buildout period of the generator is beyond the traffic design year.)

(Note: If upon completion of Step 2 it is determined that the traffic forecasts capture the effects of the proposed land use, it may still be desirable to complete this step because the results may be needed to develop and evaluate site access-related improvements.)

Step 4: Adjust Traffic Forecast to Account for Impacts of Proposed Land Use

If the results of Step 2 indicate that the traffic forecast needs to be adjusted to account for the proposed land-use impacts, the adjustment is accomplished by simply adding the traffic generated by the development in the design year (as estimated in Step 3) to the

traffic forecast developed in Step 2. Estimates of the percent trucks in the design year traffic, design hour volumes, directional distribution of the traffic, and other design-related factors should be developed in accordance with standard Department practice.

Step 5: Conduct Level of Service/Alternatives Analysis Using Adjusted Forecast

The ability of the existing roadway(s) in the study corridor to accommodate the projected traffic volumes should be assessed using the Department's standard level of service analysis procedures. The results of this analysis provide an indication of the need for additional capacity which may be needed along various segments of the roadways in the study corridor. Alternative design and/or operations-related solutions to any capacity deficiencies should be developed and evaluated on the basis of the Department's highway project evaluation criteria. Application of these criteria should result in the identification of the "preferred solution."

Step 6: Develop Roadway Design(s)

Preliminary and final designs for the preferred alternative should be prepared in accordance with standard Department policies and procedures.

Step 7: Document Findings

The results of the study should be documented and distributed in accordance with standard Department policies and procedures.

Trip Generation (3).

EXHIBIT D-2: GLOSSARY

GLOSSARY[2]

Average Trip Rate. A weighted average of the number of trips or trip ends per unit of related independent variable (e.g., trip ends per dwelling unit or employee). The average rate is calculated by summing all trips or trip ends and all independent variables where paired data are available and then dividing the trip sum by the sum of the independent variables to obtain a weighted average.

Average Trip Rate for Peak Hour of Adjacent Street Traffic. The weighted average trip rate during the hour of the highest volume of traffic passing the site on adjacent streets between 7 and 9 A.M. or between 4 and 6 P.M.

Average Trip Rate for Peak Hour of Generator. The weighted average trip rate during the hour of highest volume of traffic entering and exiting the study site in the A.M. or in the P.M. It may or may not coincide in time or volume with the trip rate for the peak hour of the adjacent street traffic.

Average Weekday Vehicle Trips Ends (AWDVTE). The weighted 24-hour total of all vehicle trips counted to and from a study site from Monday through Friday.

Correlation Coefficient (R). A measure of the degree of linear association between two variables. The correlation coefficient indicates the degree to which the model estimated values account for the deviations in the individual observed values of the independent variable from their mean value. Numerical magnitudes for "least squares" models range from -1 to +1 with larger absolute values representing higher degrees of linear association. The correlation coefficient for rate models is undefined when the use of a constant of trips is better than the use of the rate model (a condition that does not occur with least squares models).

Gross Floor Area. The gross floor area of a building is the sum of the area at each floor level, including cellars, basements, mezzanines, penthouses, corridors, lobbies, stores, and offices, that are included within the principal outside faces of exterior walls, not including architectural setbacks or projections. Included are stories or areas that have floor surfaces with clear standing head room (6 feet, 6 inches, minimum) regardless of their use. Where a ground level area, or part thereof, within the principal outside faces of the exterior walls is left unenclosed, the gross area of the unenclosed portion is to be considered as a part of the overall square footage of the building. All unroofed areas and unenclosed roofed-over spaces, except as defined above, are to be excluded from the area calculations.

For purposes of the trip generation calculation, the gross area of any parking garages within the building shall not be included within the gross area of the entire building. The gross area of the entire building shall be referred to as the gross square feet of the building.

---

[2]Definitions are taken from **Trip Generation**, (4th Ed.), Institute of Transportation Engineers, 1987.

Gross Leasable Area (GLA). Gross leasable area is the total floor area designed for tenant occupancy and exclusive use, including any basements, mezzanines, or upper floors, expressed in square feet and measured from the centerline of joint partitions and from outside wall faces. Gross leasable area is all that area for which tenants pay rent; it is the area that produces income. GLA lends itself readily to measurement and comparison. Because of this feature, GLA has been adopted by the shopping center industry as its standard for statistical comparison.

Gross Rentable Area. Gross rentable area shall be computed by measuring inside finish of permanent outer building walls, or from the glass line where at least 50% of the outer building wall is glass. Gross rentable area shall include all area within outside walls less stairs, elevator shafts, flues, pipe shafts, vertical ducts, and balconies.

Independent Variable. A physical, measurable, and predictable unit quantifying the study site or generator (e.g., building area, employees, seats, acres, dwelling units).

Mixed-Use Development. A mixed-use development means a relatively large scale real estate project characterized by: 1) Three or more significant revenue-producing uses (such as retail, office, residential hotel/motel, and recreation which in well-planned projects are mutually supporting); 2) Significant functional and physical integration of project components (and thus a highly intensive use of land), including uninterrupted pedestrian connections; and 3) Development in conformance with a coherent plan (which frequently stipulates the type and scale of uses, permitted densities, and related items).

Net Rentable Area. Net rentable area shall be computed by measuring inside finish of permanent outer building walls or from glass line where at least 50% of the outer building wall is glass. Net rentable area shall include all area within outside walls less stairs, elevator shafts, flues, pipe shafts, vertical ducts, balconies, air conditioning rooms, janitorial closets, electrical closets, washrooms, public corridors, and such other rooms not actually available to the tenant for his furnishings and personnel and their enclosing walls. No deductions shall be made for columns and projections necessary to the building.

Office Building Size. The unit of measure of office buildings is currently the gross floor area; however, in the future, data related to gross rentable and net rentable area will be obtained and incorporated into **Trip Generation.**

Regression Equation. An expression of the optimal mathematical relationship between two or more related items (variables) according to a specified criterion, as: $Y = a + bX$. The objective in developing the relationship between X (independent variable) and Y (dependent variable) is to determine values of the parameters "a" and "b" so that the expected error involved in estimating the dependent variable, given estimates of the independent variable, will be a minimum.

Trip. A single or one-direction vehicle movement with either the origin or destination (exiting or entering) inside the study site.

Trip Ends. The total of all trips entering plus all trips leaving a designated land-use or building type over a given period of time.

ALTERNATIVE TRAFFIC DIVERSION METHODOLOGIES

ALTERNATIVE TRAFFIC DIVERSION METHODOLOGIES

BPR DIVERSION CURVE

Figure E-1 shows a traffic diversion curve based on time ratio which has been developed from studies of diversion to free limited access highways made by the Bureau of Public Roads (BPR) and others. It should be considered as applicable to free limited access highways in both rural and urban areas and to both passenger cars and trucks.

From this curve, the percentage of the trips between any pair of zones that will be diverted to the freeway can be estimated if the travel times via the old route and via the freeway are known. For example, if the time ratio is 1.0, i.e., the traveltime is equal between a pair of zones by the two routes (the distance, of course, being greater via the freeway), the curve shows that 40 percent of the trips between these zones will use the freeway; if there is a 20 percent time savings via the freeway (time ratio 0.80), it shows that 73 percent of the trips will be diverted to the freeway.

To make use of the traffic diversion curve, a knowledge of the number of trips between different origins and destinations is necessary. Origin and destination surveys have been made within most of the larger cities and on external cordons around many of the smaller ones. Although these surveys were made in different years, the data can be used as a basis for making the estimates if due consideration is given to the developments that have taken place since the date of the survey.

In the absence of complete origin and destination data, approximations will need to be made, and a knowledge of the percentage distribution of trip lengths in relation to distance between interchanges will be helpful. It is strongly recommended, however, that roadside interviews be conducted at crucial points for short periods especially where there exist unusual uncertainties with regard to the trip length distribution or because a relatively small change in the traffic forecast would result in a major change in the design, such as from 4 to 6 lanes.

Ranges in the percentages of diversion from a single road closely parallel to the freeway route, for vehicles of different types, are summarized as follows:

Type of Vehicle	Diversion Percentage
Local Passenger Cars	55% - 80%
Out of State Passenger Cars	80% - 90%
Single-Unit Trucks	55% - 80%
Truck Combinations	85% - 95%

DIAL'S PROBABILISTIC DIVERSION PROCEDURE

Dial's procedure, as described in NCHRP Report No. 187, can be used to assess the general magnitude of traffic diversion resulting from projects that reduce travel time on an existing roadway. The required equations for the usual two competing route problem (see NCHRP 187 for analyzing three competing routes) are as follows:

$$V_{mtr} = [1/(1 + e^{\theta} (t_m - t_i)] V_T$$

$$V_i = [e^{\theta} (t_m - t_i)/(1 + e^{\theta} (t_m - t_i))] V_T$$

$$\theta = \ln (V_i/V_{mtr})/(t_m - t_i)$$

where:

V_{mtr}	=	volume on minimum time route
θ	=	diversion parameter
t_m	=	time on minimum time route
t_i	=	time on alternate route [Note: $(t_m - t_i)$ is always negative]
V_T	=	total volume on two facilities ($V_T = V_{mtr} + V_i$)
V_i	=	volume on alternate route
e	=	base of natural logarithms

The following example and worksheet illustrate the application of the procedure:

Route A

Base (before improvement) Travel Time	=	8.6 minutes
Base (before improvement) Volume	=	10,000 veh/day (VPD)
Revised (after improvement) Travel Time	=	6.0 minutes

Route B

Base Travel Time	=	7.5 minutes
Base Volume	=	8,500 veh/day

Calculation of Diversion Parameter (θ)

(1)	Volume on Slow Route (Base Condition)	10,000 VPD
(2)	Volume on Fast Route (Base Condition)	8,500 VPD
(3)	Line 1/Line 2	0.85
(4)	Natural log (ln) of Line 3	-0.163

(5)	Travel Time on Fast Route (Base Condition)	7.5 Minutes
(6)	Travel Time on Slow Route (Base Condition)	8.6 Minutes
(7)	Line 5 - Line 6	-1.1 Minutes
(8)	Line 4/Line 7 (Diversion Parameter, θ)	0.148

Adjusted Volume

(9)	Total Volume on Both Routes (Line 1 + Line 2)	18,500 VPD
(10)	Travel Time on Fast Route (Revised Condition)	6.0 Minutes
(11)	Travel Time on Slow Route (Revised Condition)	7.5 Minutes
(12)	Line 10 - Line 11	-1.5
(13)	Line 8 X Line 12	-0.222
(14)	$1 + 2.7183^{(\text{value from line 13})}$	1.80
(15)	1/Line 14	0.555
(16)	Line 9 x Line 15 (Volume on Fast Route)	10,270
(17)	Line 9 - Line 16 (Volume on Slow Route)	8,320

In this example, the travel time savings resulting from improvements to Route A would be sufficient to cause an estimated 270 veh/day to divert from Route B to Route A.
