INTRODUCTION

District 23 uses a modified Kearby method of designing asphalt surface treatments. The design begins with a spreading of aggregate on a measured surface to determine the rate of aggregate for a single rock depth application, similar to Texas Test Method Tex 216-F. The asphalt design rate of application varies according to traffic volume, surface condition, desired embedment, type of asphalt, etc. The design is based on wheel path condition or anticipated wheel application and the asphalt quantities are varied transversely across the roadway depending on the surface condition near the edge of the lanes and between the wheel paths. The basic design is formulated in the office but from visual observations of the roadway surface, however, the design may be slightly adjusted during construction by the field supervisor to fit specific roadway conditions. A form has been prepared to aid in developing and documenting the design. The form allots a portion of space for test records for all tests on bituminous surfaces and is shown in Appendix A.

Our governing specifications require the contractors to provide nozzle sizes that permit variation of the asphalt transversely. Generally, the amount of asphalt is designed for the wheel path and more asphalt is provided in other areas to prevent raveling.

The Asphalt Institute publishes a chart giving the proper nozzle height above the road for the recommended lap of spray. Therefore, nozzle size (and possibly angle) maybe varied for the proper amount of asphalt transversely across the surface. (See Figures 1 and 2)

The 1977 seal coat program consisted of approximately 300 miles let in four contracts. During the initial surfacing on one contract, a considerable amount of streaking was noted. A number of things were

| NOZZLE SIZE | NOZZLE SPACING | NOZZLE SLOT ANGLE | NOZZLE HEIGHT ABOVE ROAD | PUMP DISCHARGE - GALS. PER MIN. OR PUMP SPEED | PUMP PRESSURE | APPLICATION RATE GAL. PER SQ. YD. | COVERAGE |

Distributor - ETNYRE

FIGURE 1

SUGGESTED NOZZLE DISTRIBUTION INFORMATION AFTER ASPHALT INSTITUTE

Oct., 1966

FIGURE 2—SLOT ANGLES AND LAPS FROM THE DHT CONSTRUCTION MANUAL

checked to determine the cause of the streaking. Among these were the height of the spray bar, the slot angle of the nozzle and the pump pressures. After these studies did not provide acceptable clues, we observed the fans on the nozzles were not uniform. All the nozzles were removed from the Etnyre distributor and brought to the district laboratory to check each fan width. The correct width should have been 13.86 inches with a 30 degree slot angle and a triple lap.

CHAPTER

II

NOZZLE FAN WIDTH TEST

A test was developed to check the nozzles used in asphalt distributors. This test permitted the visual observation of a single nozzle and the resultant distribution characteristics of the nozzle. Figure 3 shows the test method set up. The test permits the nozzle in question to be attached to flexible tubing and the nozzle height to be adjusted. Water is forced through the nozzle at a selected pressure. By placing the nozzle in front of a darkened background and using the correct lighting, the fan distribution can be observed and the fan width measured. Of course water has a different viscosity as compared to the emulsified asphalt being used, however, it has been observed that once a certain water pressure (or water velocity) has been achieved the fan width is constant. This pressure is approximately 5 psi. Also, by observation, the viscosity of water and the heated emulsion are not greatly different. Using these two facts along with the test, the expected spray width can be predicted with a fair degree of accuracy, however, variation between nozzles can certainly be observed.

Each of the nozzles from the distributor were checked using the test described above. The following is the results of this check:

| <u>No. of Nozzles</u> | <u>Spray Width</u> |
|-----------------------|--------------------|
| 1 | 10" |
| 5 | 11" |
| 17 | 12" |
| 6 | 13" |
| 3 | 14" |
| 3 | 22" |

FIGURE 3 - NOZZLE SPRAY WIDTH TEST

Only 9 of the 35 nozzles checked were within 10% of the desired spray width. It is evident that with this spray pattern no uniform transverse distribution could be achieved.

To have better control of the transverse distribution, the district's plan was to provide the contractor with a new set of nozzles for use while applying asphalt in our area. To accomplish this, we purchased fifty 1/8" and fifty 3/32" Etnyre nozzles. These nozzles were checked in our laboratory for uniformity in spray pattern. The correct fan for these nozzles should have been the same as above (13.86") and the following results were found for these new nozzles:

| <u>1/8 in. Nozzle</u> | | <u>3/32 in. Nozzle</u> | |
|-----------------------|--------------------|------------------------|--------------------|
| <u>No. of Nozzles</u> | <u>Spray Width</u> | <u>No. of Nozzles</u> | <u>Spray Width</u> |
| 8 | 12" | 1 | 14" |
| 26 | 13" | 2 | 20" |
| 8 | 14" | 4 | 21" |
| 2 | 15" | 3 | 22" |
| 1 | 17" | 8 | 23" |
| 2 | 18" | 24 | 24" |
| 1 | 21" | 8 | 26" |
| 1 | 22" | | |
| 1 | 24" | | |

The Etnyre Distributor Company that furnished these nozzles was contacted and advised of our finding. They requested that all of the 3/32 in. nozzles be returned to their supply. They in turn would check 50 more 3/32 in. nozzles and furnish good nozzles in their place.

I I I

BUCKET TEST

In addition to checking the spray width of the nozzles, a test was devised to check the quantity of asphalt delivered by each nozzle along the spray bar. This type of test is not new, for example the "Construction Manual" suggests using strips of thin, foil-backed insulation material and weighing the strips before and after application to determine quantity. However, the district has difficulty in obtaining adequate repeatability in using the insulation material. In the bucket test to be described, discarded triaxial cells previously used in triaxial tests were shortened to an eight-inch height and crushed slightly to form an oval cylinder rather than a cylindrical cylinder. The oval cylinder was fitted with a base or bottom by welding the cylinder to a presized metal plate. This presized metal plate was fabricated from the removed upper portion of the cylinder. In other words, an oval metal container was fabricated (see Figure 4). The hole originally designed to permit lateral pressure was welded closed. Sufficient containers were fabricated so that a container could be placed under each nozzle on the spray bar. Each container was fitted with a plastic bag to catch the asphaltic material and to facilitate the cleaning of the container. A tare weight was obtained for each cylinder. The asphalt in the distributor was heated and circulated. The spray bar was "blown" or the emulsion sprayed for a short period of time and the prepared containers were placed under each nozzle. The containers should be placed in a manner to catch all the emulsion to be emitted in the test without affecting the tare weight. The emulsion was released through the spray bar-nozzles into the containers. The containers were then weighed to determine the asphalt quantity emitted by each nozzle. (see Figure 5) This procedure is normally used to check a distributor entering the district but it could be used at any time.

FIGURE 4 - CONTAINER FOR BUCKET TEST

FIGURE 5 - BUCKET TEST

The transverse distribution can be checked using this test to assure the design quantities are being received. However, the calculations should be based on the desired percentage difference between the nozzles in selected regions of the spray bar. These regions may be seven or eight nozzles in the wheel path area as versus the group of nozzles in the region near the lane edges or between the wheel paths. The test is not truly precise and some variation in repeatability of single nozzles exists. An excellent example of the use of this test occurred when comparing the distribution of a long or extended spray bar with a short or nonextended bar. The standard specifications permit a 26-foot spray bar length which generally covers two lanes. Normally most engineers permit only single lane coverage using a bar length of 12 to 15 feet. A test was recently conducted comparing the distribution of a 21-foot bar and a 13-foot bar using the same distributor. The results are shown in Figure 6 with the data obtained shown in Appendix B. The 21-foot bar produced greater quantities in the center 10 to 12-foot portion as compared to the quantities at each end. In other words, for the distributor tested, there was a distinct pressure drop at each end of the bar. However, the distribution rate for the shorter bar shows a smaller variation which is random along the bar.

At present, the district is still considering furnishing nozzles to the contract distributors working in our area. Most of the contractors use Etnyre distributors, and this procedure is believed to be the most practical method of assuring the desired transverse distribution. Observations of the nozzles indicate the defective nozzles have been "milled" or keyed" with slots of varying lengths. When the slot length is shorter (a larger dimension between edge of slot and edge of nozzle) shorter fan widths were found. Longer slot lengths gave longer fan lengths when nozzles were maintained at a constant height. Figure 7 shows this observation. After discussions, the D-4 shops agreed to experiment with several of the nozzles. Several nozzles were re-milled to produce different

FIGURE 6—EXAMPLE OF PRESSURE DROP WHEN USING LONG SPRAY BAR

FIGURE 7—SCHEMATIC OF LARGER AND SMALLER FAN WIDTHS

quantities of asphalt. A request has been made to D-4 to obtain nozzles with a $9/64$, $5/32$, $11/64$ and $3/16$ - inch slot widths in order that more specific asphalt quantities may be achieved with individual nozzles. The district evaluates and places each nozzle in a fan width group for later use. Therefore, nozzles with correct fan width and output quantities can be selected for the desired transverse distribution.

Referring to fan widths, it is possible to achieve correct spray coverage by combining nozzles of varying spray widths but set at varied and pre-calculated slot angles. However, it would be simpler to use nozzles with a constant spray width as suggested by the Asphalt Institute and set at a constant slot angle. The height may be varied to achieve the desired lap.

CHAPTER

IV

CONCLUSIONS AND RECOMMENDATIONS

Since each job is unique it is necessary that the engineer be given the freedom and authority to conduct the construction processes to produce the best job possible. Therefore, it is believed the present specifications are adequate. However, it is recommended that the engineering staff in District 23 consider the following in seal coat or surface treatment construction:

1. Use of extended spray bars should not be permitted until a check has been made using the Bucket Test. The percent variation from the mean should be random when comparing nozzle output along the bar. The percent variation from the mean of any individual nozzle should not be greater than ± 10 percent.
2. Distributor nozzles should be checked using the Bucket Test and the percent variation from the mean of any nozzle should not be greater than ± 10 percent.
3. Distributor nozzles should be checked using the Nozzle Fan Width Test and any individual nozzle should not vary from the desired spray width by more than ± 10 percent.

In summary, the proper fan and distribution of asphalt distributor nozzles is essential to provide proper lap and quantities at the recommended height and District 23 plans to check all nozzles of the distributors used in the area prior to the application of asphalt. Perhaps with increased attention to nozzles along with the improved design procedures available longer lasting and better surfaces will result.
